Preface

This book describes extensions to the Open Object Rexx Interpreter that are specific to the Windows operating system. The extensions are in two main categories.

The first category is a number of classes implemented in a library package, **winSystem.cls**. These classes are used to interact with Windows system objects like the event log and the clipboard. The second category is OLE Automation ([Chapter 8, OLE Automation](#)).

These extensions are currently only available on Windows. The Windows Scripting Host and OLE Automation can only be implemented on Windows. Some of the classes, such as the WindowsEventLog ([Chapter 4, The WindowsEventLog Class](#)) and the WindowsRegistry ([Chapter 3, The WindowsRegistry Class](#)) classes must be, by their nature, Windows specific. Some of the other classes, such as the MenuObject ([Chapter 7, The MenuObject Class](#)) or WindowObject ([Chapter 6, The WindowObject Class](#)) classes could certainly be enhanced to be cross-platform. However, at this time there are no plans to do so.

This book is intended for people who plan to develop applications using ooRexx and one or more of the Windows specific classes. In general no special knowledge of Windows programming is needed to use the Windows extensions. Therefore this book is applicable for users ranging in experience from the novice ooRexx programmer, to the experienced application developer.

This book is a reference rather than a tutorial. It assumes the reader has some exposure to object-oriented programming concepts and Rexx programming.

The use and syntax of all the classes and their methods is covered in this book. A brief overview of OLE Automation and the Windows Scripting Host Engine is given. Many of the descriptions of class methods also include example code snippets.

1. Document Conventions

This manual uses several conventions to highlight certain words and phrases and draw attention to specific pieces of information.

1.1. Typographic Conventions

Typographic conventions are used to call attention to specific words and phrases. These conventions, and the circumstances they apply to, are as follows.

Mono-spaced Bold is used to highlight literal strings, class names, or inline code examples. For example:

The **Class** class comparison methods return **.true** or **.false**, the result of performing the comparison operation.

This method is exactly equivalent to **subWord(*n*, 1)**.

Mono-spaced Normal denotes method names or source code in program listings set off as separate examples.

This method has no effect on the action of any `hasEntry`, `hasIndex`, `items`, `remove`, or `supplier` message sent to the collection.

```
-- reverse an array
a = .Array-of("one", "two", "three", "four", "five")
```

```
-- five, four, three, two, one
aReverse = .CircularQueue~new(a~size)~appendAll(a)~makeArray("lifo")
```

Proportional Italic is used for method and function variables and arguments.

A supplier loop specifies one or two control variables, *index*, and *item*, which receive a different value on each repetition of the loop.

Returns a string of length *length* with *string* centered in it and with *pad* characters added as necessary to make up length.

1.2. Notes and Warnings

Finally, we use three visual styles to draw attention to information that might otherwise be overlooked.

Note

Notes are tips, shortcuts or alternative approaches to the task at hand. Ignoring a note should have no negative consequences, but you might miss out on a trick that makes your life easier.

Important

Important boxes detail things that are easily missed, like mandatory initialization. Ignoring a box labeled 'Important' will not cause data loss but may cause irritation and frustration.

Warning

Warnings should not be ignored. Ignoring warnings will most likely cause data loss.

2. How to Read the Syntax Diagrams

Throughout this book, syntax is described using the structure defined below.

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

The ► symbol indicates the beginning of a statement.

The ---- symbol indicates that the statement syntax is continued on the next line.

The ---- symbol indicates that a statement is continued from the previous line.

The ► symbol indicates the end of a statement.

- Required items appear on the horizontal line (the main path).

- Optional items appear below the main path.

- If you can choose from two or more items, they appear vertically, in a stack. If you must choose one of the items, one item of the stack appears on the main path.

- If choosing one of the items is optional, the entire stack appears below the main path.

- If one of the items is the default, it is usually the topmost item of the stack of items below the main path.

- A path returning to the left above the main line indicates an item that can be repeated.

A repeat path above a stack indicates that you can repeat the items in the stack.

- A pointed rectangle around an item indicates that the item is a fragment, a part of the syntax diagram that appears in greater detail below the main diagram.

- Keywords appear in uppercase (for example, **SIGNAL**). They must be spelled exactly as shown but you can type them in upper, lower, or mixed case. Variables appear in all lowercase letters (for example, *index*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or such symbols are shown, you must enter them as part of the syntax.

The following example shows how the syntax is described:

3. Getting Help and Submitting Feedback

The Open Object Rexx Project has a number of methods to obtain help and submit feedback for ooRexx and the extension packages that are part of ooRexx. These methods, in no particular order of preference, are listed below.

3.1. The Open Object Rexx SourceForge Site

Open Object Rexx utilizes SourceForge to house its source repositories, mailing lists and other project features at <https://sourceforge.net/projects/ooress>. ooRexx uses the Developer and User mailing lists at <https://sourceforge.net/p/ooress/mailman> for discussions concerning ooRexx. The ooRexx user is most likely to get timely replies from one of these mailing lists.

Here is a list of some of the most useful facilities provided by SourceForge.

The Developer Mailing List

Subscribe to the ooress-devel mailing list at <https://sourceforge.net/projects/ooress/lists/ooress-devel> to discuss ooRexx project development activities and future interpreter enhancements. You can find its archive of past messages at <https://sourceforge.net/p/ooress/mailman/ooress-devel>.

The Users Mailing List

Subscribe to the ooress-users mailing list at <https://sourceforge.net/projects/ooress/lists/ooress-users> to discuss how to use ooRexx. It also supports a historical archive of past messages.

The Announcements Mailing List

Subscribe to the ooress-announce mailing list at <https://sourceforge.net/projects/ooress/lists/ooress-announce> to receive announcements of significant ooRexx project events.

The Bug Mailing List

Subscribe to the ooress-bugs mailing list at <https://sourceforge.net/projects/ooress/lists/ooress-bugs> to monitor changes in the ooRexx bug tracking system.

Bug Reports

You can view ooRexx bug reports at <https://sourceforge.net/p/ooress/bugs>. To be able to create new bug reports, you will need to first register for a SourceForge userid at <https://sourceforge.net/user/registration>. When reporting a bug, please try to provide as much information as possible to help developers determine the cause of the issue. Sample program code that can reproduce your problem will make it easier to debug reported problems.

Documentation Feedback

You can submit feedback for, or report errors in, the documentation at <https://sourceforge.net/p/ooress/documentation>. Please try to provide as much information in a documentation report as possible. In addition to listing the document and section the report concerns, direct quotes of the text will help the developers locate the text in the source code for the document. (Section numbers are generated when the document is produced and are not available in the source code itself.) Suggestions as to how to reword or fix the existing text should also be included.

Request For Enhancement

You can suggest new ooRexx features or enhancements at <https://sourceforge.net/p/ooress/feature-requests>.

Patch Reports

If you create an enhancement patch for ooRexx please post the patch at <https://sourceforge.net/p/ooress/patches>. Please provide as much information in the patch report as possible so that the developers can evaluate the enhancement as quickly as possible.

Please do not post bug fix patches here, instead you should open a bug report at <https://sourceforge.net/p/ooress/bugs> and attach the patch to it.

The ooRexx Forums

The ooRexx project maintains a set of forums that anyone may contribute to or monitor. They are located at <https://sourceforge.net/p/ooress/discussion>. There are currently three forums available: Help, Developers and Open Discussion. In addition, you can monitor the forums via email.

3.2. The Rexx Language Association Mailing List

The Rexx Language Association maintains a forum at <https://groups.io/g/rexxla-members/topics>.

4. Related Information

See also: *Open Object Rexx: Reference*

The WindowsProgramManager Class

The **WindowsProgramManager** class allows the programmer to interact with the Windows Program Manager. This class can be use to create program groups and shortcuts to access your programs.

The WindowsProgramManager class is defined in the file **winSystem.cls** To use this class in a program, place a **::requires** statement in the program file:

```
::requires "winSystem.cls"
```

A sample program **desktop.rex** is provided in the **samples\oodialog\winsystem** directory.

Methods of the WindowsProgramManager class are:

Table 1.1. Methods Available to the WindowsProgramManager Class

Method...	...link
new (Class method)	init (Section 1.1, "new (Class method)") (Class method)
addDesktopIcon	addDesktopIcon (Section 1.2, "addDesktopIcon")
addGroup	addGroup (Section 1.4, "addGroup")
addItem	addItem (Section 1.5, "addItem")
addShortCut	addShortCut (Section 1.3, "addShortCut")
deleteDesktopIcon	deleteDesktopIcon (Section 1.6, "deleteDesktopIcon")
deleteGroup	deleteGroup (Section 1.7, "deleteGroup")
deleteItem	deleteItem (Section 1.8, "deleteItem")
showGroup	showGroup (Section 1.9, "showGroup")

1.1. new (Class method)

Creates an instance of the WindowsProgramManager class.

1.2. addDesktopIcon

Adds a shortcut to the Windows desktop. A sample program **DESKICON.REX** is provided in the **ooRexx\SAMPLES** directory.

Arguments:

The arguments are:

name

The name of the shortcut, displayed below the icon.

program

The program file launched by the shortcut.

iconfile

The name of the icon used for the shortcut. If not specified, the icon of *program* is used.

iconnr

The number of the icon within the *iconfile*. The default is 0.

workdir

The working directory of the shortcut.

location

Either of the following locations:

"PERSONAL"

The shortcut is personal and displayed only on the desktop of the user.

"COMMON"

The shortcut is common to all users and displayed on the desktop of all users.

args

The arguments passed to the program that the shortcut refers to.

hotkey

The virtual key to be used as a hotkey to open the shortcut. For a list of the key names, see [Section 1.10, "Symbolic Names for Virtual Keys"](#).

run

Specifies one of the options listed in the syntax diagram. The default is "NORMAL".

1.3. addShortCut

Creates a shortcut within the specified folder.

Arguments:

The arguments are:

name

The full name of the shortcut.

program

The program file launched by the shortcut.

iconfile

The name of the icon used for the shortcut. If not specified, the icon of *program* is used.

iconnr

The number of the icon within the *iconfile*. The default is 0.

workdir

The working directory of the shortcut.

args

The arguments passed to the program that the shortcut refers to.

hotkey

The virtual key to be used as a hotkey to open the shortcut. For a list of the key names, see [Section 1.10, "Symbolic Names for Virtual Keys"](#).

run

Specifies one of the options listed in the syntax diagram. The default is "NORMAL".

Example:

The following example creates a shortcut named "My NotePad" to the Notepad editor within the directory c:\temp:

Example 1.1. WindowsProgramManager class - addShortCut method

```
pm = .WindowsProgramManager~new
if pm~InitCode \= 0 then exit
pm~addShortCut("c:\temp\My Notepad", "%SystemRoot%\system32\notepad.exe")
::requires "winsystem.cls"
```

1.4. addGroup

Adds a program group to the Programs group of the desktop. If the group already exists, it is opened. The *group* argument specifies the name of the program group to be added. Example:

```
addGroup("Object Rexx Redbook")
```

Note

The name that you specify for the *group* argument must not contain any brackets or parenthesis. Otherwise, this method fails.

Return value:

0

The method was successful.

1

The method failed.

1.5. addItem

Adds a shortcut to a program group. The shortcut is placed into the last group used with either AddGroup or ShowGroup.

Example 1.2. WindowsProgramManager class - addItem method

```
AddItem("OODialog Samples", ,
"rexx oodialog\samples\sample.rex", ,
"oodialog\samples\oodialog.ico")
```

Note

The name that you specify for the *group* argument must not contain characters that are not valid, such as brackets or parenthesis. Otherwise, this method fails. Some characters are changed, for example / to _.

Return value:

0

The method was successful.

1

The method failed.

1.6. deleteDesktopIcon

Deletes a shortcut from the Windows desktop that was previously created with AddDesktopIcon.

The arguments are:

name

The name of the shortcut to be deleted.

location

Either of the following locations:

"PERSONAL"

The shortcut was previously created with AddDesktopIcon and the location option "PERSONAL". This is the default.

"COMMON"

The shortcut was previously created with AddDesktopIcon and the location option "COMMON".

Return codes:

- 0
Shortcut deleted successfully.
- 2
Shortcut not found.
- 3
Path to shortcut not found.
- 5
Access denied or busy.
- 26
Not a DOS disk.
- 32
Sharing violation.
- 36
Sharing buffer exceeded.
- 87
Does not exist.
- 206
Shortcut name exceeds range error.

**Note:**

Return code 2 is also returned when a "PERSONAL" should be deleted that was previously created with "COMMON" and vice versa.

Example 1.3. WindowsProgramManager class - deleteDesktopIcon method

```
pm = .WindowsProgramManager~new
if pm~InitCode \= 0 then exit

rc = pm~deleteDesktopIcon("MyNotepad1", ,
    "%SystemRoot%\system32\notepad.exe")
if rc \= 0 then do
    say "Error deleting shortcut: My Notepad 1"
    exit
end

exit

::requires "winsystem.cls"
```

1.7. deleteGroup

Deletes a program group from the desktop. The *group* argument specifies the name of the program group to be deleted.

Return value:

- 0
The method was successful.
- 1
The method failed.

1.8. deleteItem

Deletes a shortcut from a program group.

Return value:

- 0
The method was successful.
- 1
The method failed.

1.9. showGroup

Opens a program group. The *group* argument specifies the name of the program group to be opened. If MIN or MAX is specified, the program group is opened minimized or maximized.

Return value:

0

The method was successful.

1

The method failed.

1.10. Symbolic Names for Virtual Keys

[Table 1.2, “Symbolic Names for Virtual Keys”](#) shows the symbolic names and the keyboard equivalents for the virtual keys used by Object Rexx.

Table 1.2. Symbolic Names for Virtual Keys

Symbolic Name	Mouse or Keyboard Equivalent
LBUTTON	Left mouse button
RBUTTON	Right mouse button
CANCEL	Control-break processing
MBUTTON	Middle mouse button (three-button mouse)
BACK	BACKSPACE key
TAB	TAB key
CLEAR	CLEAR key
RETURN	ENTER key
SHIFT	SHIFT key
CONTROL	CTRL key
MENU	ALT key
PAUSE	PAUSE key
CAPITAL	CAPS LOCK key
ESCAPE	ESC key
SPACE	SPACEBAR
PRIOR	PAGE UP key
NEXT	PAGE DOWN key
END	END key
HOME	HOME key
LEFT	LEFT ARROW key
UP	UP ARROW key
RIGHT	RIGHT ARROW key

Symbolic Name	Mouse or Keyboard Equivalent
DOWN	DOWN ARROW key
SELECT	SELECT key
EXECUTE	EXECUTE key
SNAPSHOT	PRINT SCREEN key
INSERT	INS key
DELETE	DEL key
HELP	HELP key
0	0 key
1	1 key
2	2 key
3	3 key
4	4 key
5	5 key
6	6 key
7	7 key
8	8 key
9	9 key
A	A key
B	B key
C	C key
D	D key
E	E key
F	F key
G	G key
H	H key
I	I key
J	J key
K	K key
L	L key
M	M key
N	N key
O	O key
Q	Q key
R	R key
S	S key
T	T key
U	U key
V	V key

Symbolic Name	Mouse or Keyboard Equivalent
W	W key
X	X key
Y	Y key
Z	Z key
NUMPAD0	Numeric keypad 0 key
NUMPAD1	Numeric keypad 1 key
NUMPAD2	Numeric keypad 2 key
NUMPAD3	Numeric keypad 3 key
NUMPAD4	Numeric keypad 4 key
NUMPAD5	Numeric keypad 5 key
NUMPAD6	Numeric keypad 6 key
NUMPAD7	Numeric keypad 7 key
NUMPAD8	Numeric keypad 8 key
NUMPAD9	Numeric keypad 9 key
MULTIPLY	Multiply key
ADD	Add key
SEPARATOR	Separator key
SUBTRACT	Subtract key
DECIMAL	Decimal key
DIVIDE	Divide key
F1	F1 key
F2	F2 key
F3	F3 key
F4	F4 key
F5	F5 key
F6	F6 key
F7	F7 key
F8	F8 key
F9	F9 key
F10	F10 key
F11	F11 key
F12	F12 key
F13	F13 key
F14	F14 key
F15	F15 key
F16	F16 key
F17	F17 key
F18	F18 key

Symbolic Name	Mouse or Keyboard Equivalent
F19	F19 key
F20	F20 key
F21	F21 key
F22	F22 key
F23	F23 key
F24	F24 key
NUMLOCK	NUM LOCK key
SCROLL	SCROLL LOCK key

The WindowsClipboard Class

The WindowsClipboard class provides methods to interact with a clipboard. Typically a clipboard is used to transfer data back and forth between different windows in a graphical user interface.

The WindowsClipboard class is not a built-in class. It is defined in the **winSystem.cls** file. This means, you must use a **::requires** statement to use its functionality, as follows:

```
::requires "winSystem.cls"
```

Methods the WindowsClipboard Class Defines

- copy
- makeArray
- paste
- empty
- isDataAvailable
- locale

2.1. copy

Empties the clipboard and copies the specified text to it.

If *codepage* is omitted or is an empty string, the text (which should be an ANSI string) is converted to Unicode by the system.

If *codepage* is "UNICODE", the text (which should be a UTF-16 string) is put as-is in the clipboard.

For any other value of *codepage*, the text (which should be a string encoded in *codepage*) is converted to Unicode using the Rexx utility **SysToUnicode**. The arguments *codepage* and *translateflags* are passed to **SysToUnicode**. They are described in the ooRexx reference documentation.

Example 2.1. WindowsClipboard class - copy method

```
clipboard = .WindowsClipboard~new
clipboard~copy("Noel")                -- ANSI text
clipboard~copy("4E00 6F00 EB00 6C00"x, "UNICODE") -- UTF-16 text (stored as-is)
clipboard~copy("Noël", "UTF8")         -- SysToUnicode is used
clipboard~copy("Noël", "UTF8", "ERR_INVALID_CHARS") -- SysToUnicode is used
```

2.2. makeArray

If the content of the clipboard is a string with newline characters in it, makeArray can be used to split up the string into individual lines. An array is returned containing those lines.

Note

This method is limited to the default codepage. If you need to specify a codepage then use:

```
.WindowsClipboard~new~paste("UTF8")~makeArray
```

2.3. paste

Retrieves the text data stored on the clipboard.

If *codepage* is omitted or is an empty string, the clipboard contents is converted from Unicode by the system and returned as an ANSI string.

If *codepage* is "UNICODE", the clipboard contents is returned as a UTF-16 string.

For any other value of *codepage*, the clipboard contents is converted from Unicode using the Rexx utility **SysFromUnicode** and returned as a string encoded in *codepage*. The arguments *codepage*, *mappingflags* and *defaultchar* are passed to **SysFromUnicode**. They are described in the ooRexx reference documentation.

Example 2.2. WindowsClipboard class - paste method

```

clipboard = .WindowsClipboard~new
text = clipboard~paste                -- ANSI text
text = clipboard~paste("UNICODE")    -- UTF-16 (returned as stored)
text = clipboard~paste("UTF8")        -- SysFromUnicode is used
text = clipboard~paste("CP1252", "DEFAULTCHAR", "#") -- SysFromUnicode is used

```

2.4. empty

Empties the clipboard.

2.5. isDataAvailable

Returns 1 if the text data is available on the clipboard. If no data is available, 0 is returned.

2.6. locale

Returns the locale name associated with the text in the clipboard.

For example: "de-DE_phoneb" where

- "de" is the primary language
- "DE" is the sublanguage (optional)
- "phoneb" is the sort order (optional)

The WindowsRegistry Class

The **WindowsRegistry** class allows the programmer to interface with the operating system APIs that are used to access the *registry*. The class can be used to query the registry and modify, add, and delete entries.

In the Windows operating systems, the *registry* is a system-defined database in which applications and system components store and retrieve configuration data. The data stored in the registry varies according to the version of Microsoft Windows. Applications use the registry APIs to retrieve, modify, or delete registry data.

You should not edit registry data that does not belong to your application unless it is absolutely necessary. If there is an error in the registry, your system may not function properly. If this happens, you can restore the registry to the state it was in when you last started the computer successfully. For more information, see the help for your operating system.

The registry stores data in a tree format. Each node in the tree is called a key. Each key can contain both subkeys and data entries called values. Sometimes, the presence of a key is all the data that an application requires; other times, an application opens a key and uses the values associated with the key. A key can have any number of values, and the values can be in any form.

Each key has a name consisting of one or more printable characters. Key names are not case sensitive. Key names cannot include a backslash (\), but any other printable or unprintable character can be used. The name of each subkey is unique with respect to the key that is immediately above it in the hierarchy. Key names are not localized into other languages, although values may be.

Note: Windows provides a command line user tool named **regedit** that displays the registry and its tree structure on the local machine. The tool can be very helpful in picturing the layout of the registry. To use it, merely type **regedit** at the command prompt of a console window, or use the *run* option of the **Start** menu.

Most of the operating system functions that manipulate the registry require the open handle of a parent key. As a convenience to the programmer, the **WindowsRegistry** class usually allows this handle to be omitted as an argument in its methods. The class keeps track of the most recently opened handle and supplies this handle when the programmer omits the parent handle argument in a method. This mechanism is implemented through the `current_key` ([Section 3.6](#), “*current_key (Attribute [get])*”) attribute. When a method has a parent handle argument and the programmer omits the argument, the current key handle is used.

The WindowsRegistry class is not a built-in class; it is defined in the file `winSystem.cls`.

Use a `::requires` statement to use the class in a program.

```
::requires "winSystem.cls"
```

A sample program, **registry.rex**, is provided in the `samples\oodialog\winsystem` directory.

Methods the WindowsRegistry Class Defines

- `new` (Class method)
- `classes_root` (Attribute [get])
- `close`
- `create`
- `current_key` (Attribute [get])

- `current_key=` (Attribute [set])
- `current_user` (Attribute [get])
- `delete`
- `deleteKey`
- `deleteValue`
- `flush`
- `getValue`
- `list`
- `listValues`
- `load`
- `local_machine` (Attribute [get])
- `open`
- `query`
- `replace`
- `restore`
- `save`
- `setValue`
- `unload`
- `users` (Attribute [get])

3.1. new (Class method)

Creates an instance of the WindowsRegistry class. The current key is set to HKEY_LOCAL_MACHINE.

3.2. classes_root (Attribute [get])

Returns the handle of the root key HKEY_CLASSES_ROOT. This handle is maintained by the operating system, it can not be changed.

3.3. close

Closes a previously opened key specified by its handle. Example:

```
rg-close(objectrexxkey)
```

It can take several seconds before all data is written to disk. You can use FLUSH to empty the cache.

If *key_handle* is omitted, CURRENT_KEY is closed.

3.4. connect

Opens a key on a remote computer. This is supported only for HKEY_LOCAL_MACHINE and HKEY_USERS.

3.5. create

Adds a new named subkey to the registry and returns its handle. The first argument is the parent key handle. The second argument is the name of the new subkey.

Example 3.1. WindowsRegistry class - create method

```
newKey = rg-create(rg-local_machine, "myOwnKey")
```

3.6. current_key (Attribute [get])

Returns the handle of the current key. The current key is set by the new() ([Section 3.1, “new \(Class method\)”](#)) method to **HKEY_LOCAL_MACHINE**. It's value is then updated by every call to create() ([Section 3.5, “create”](#)) and open() ([Section 3.18, “open”](#)). Therefore its value is always that of the handle of the most recently opened key unless the programmer sets ([Section 3.7, “current_key= \(Attribute \[set\]\)”](#)) it to some other value.

Most registry operations require an open handle to the parent key of the subkey being operated on. In the **WindowsRegistry** class most methods that require the parent key allow the programmer to omit the parent key. When the parent key is omitted, the **current_key** handle is used.

3.7. current_key= (Attribute [set])

Sets the handle of the current key. The **WindowsRegistry** class maintains ([Section 3.6, “current_key \(Attribute \[get\]\)”](#)) this key, but the programmer can set it to any value at any time.

3.8. current_user (Attribute [get])

Returns the handle of the root key HKEY_CURRENT_USER. This handle is maintained by the operating system and can not be changed.

3.9. delete

Deletes a subkey and all its descendants. The method will remove the key, all of the key's values, and all of its subkeys from the registry. To delete a key only if the key does not have subkeys values, use the `deleteKey()` ([Section 3.10, “deleteKey”](#)) method.

Arguments

The two arguments are:

keyHandle [optional]

A handle to an open registry key. The key must have been opened with the DELETE access right. If this argument is omitted then the CURRENT_KEY attribute is used.

subkeyName [required]

The name of the subkey to be deleted. The name is case insensitive.

Return

O on success, otherwise the Windows system error code. A generic description of the error can be obtained by using the Rexx Utility function, `SysGetErrorText()`.

3.10. deleteKey

Deletes a subkey and its values from the registry. The subkey to be deleted must not have subkeys. To delete a key and all its subkeys, you need to enumerate the subkeys and delete them individually. To delete keys recursively, use the `delete()` ([Section 3.9, “delete”](#)) method.

Arguments

The two arguments are:

keyHandle [optional]

A handle to an open registry key. The key must have been opened with the DELETE access right. If this argument is omitted then the CURRENT_KEY attribute is used.

subkeyName [required]

The name of the subkey to be deleted. The name is case insensitive.

Return

O on success, otherwise the Windows system error code. A generic description of the error can be obtained by using the Rexx Utility function, `SysGetErrorText()`.

3.11. deleteValue

Deletes the named value for a given key. If `key_handle` is omitted, CURRENT_KEY is used. If `value` is blank or omitted, the default value is deleted.

3.12. flush

Forces the system to write the cache buffer of a given key to disk. If *key_handle* is omitted, CURRENT_KEY is flushed.

3.13. getValue

Retrieves the data and type for a named value of a given key. The result is a compound variable with suffixes *data* and *type*. If *key_handle* is omitted, CURRENT_KEY is used. If named *value* is blank or omitted, the default value is retrieved.

On error 0 is returned. Errors can occur, for instance, if a non-existent key is queried or if the user does not have sufficient privileges to query the key.

Example:

Example 3.2. WindowsRegistry class - getValue method

```

myval. = rg-getvalue("filesystem")      /* current key */
say "Type is" myval.type
if myval.type = "NORMAL" then say "Value is" myval.data
myval. = rg-getvalue(mykey)
say "my default value is:" myval.data
myval. = rg-getvalue(mykey,"")
say "my default value is:" myval.data
  
```

On success, possible types are: NORMAL, EXPAND, MULTI, NUMBER, BINARY, NONE, OTHER.

Since errors are possible, it may be best to test that the return is a stem before assigning the return to a stem. Something like this:

Example 3.3. WindowsRegistry class - getValue errors

```

retVal = rg~getvalue("filesystem")      /* current key */
if retVal~isA(.Stem) then do
  say "Type is" myval.type
  if myval.type = "NORMAL" then say "Value is" myval.data
else do
  say "Error getting registry value."
end
  
```

3.14. list

Retrieves the list of subkeys for a given key in a stem variable. The name of the stem variable must include the period. The keys are returned as stem.1, stem.2, and so on.

Example 3.4. WindowsRegistry class - list method

```
rg~LIST(objectrexxkey, orexxkeys.)
do i over orexxkeys.
say orexxkeys.i
end
```

3.15. listValues

Retrieves all value entries of a given key into a compound variable. The name of the variable must include the period. The suffixes of the compound variable are numbered starting with 1, and for each number the three values are the name (var.i.name), the data (var.i.data), and the type (var.i.type). The type is NORMAL for alphabetic values, EXPAND for expandable strings such as a path, NONE for no specified type, MULTI for multiple strings, NUMBER for a 4-byte value, and BINARY for any data format.

If *key_handle* is omitted, the values of CURRENT_KEY are listed.

Example 3.5. WindowsRegistry class - listValues method

```
qstem. = rg~QUERY(objectrexxkey)
rg~LISTVALUES(objectrexxkey, lv.)
do i=1 to qstem.values
say "name of value:" lv.i.name "(type="lv.i.type")"
if lv.i.type = "NORMAL" then
say "data of value:" lv.i.data
end
```

3.16. load

Load creates a named subkey under the open key *key_handle* and loads registry data from the file *filename* (created by SAVE ([Section 3.22, "save"](#))) and stores the data under the newly created subkey.

key_handle can only be HKEY_USERS or HKEY_LOCAL_MACHINE. Registry information is stored in the form of a hive - a discrete body of keys, subkeys, and values that is rooted at the top of the registry hierarchy. A hive is backed by a single file.

If *key_handle* is omitted, the subkey is created under HKEY_LOCAL_MACHINE.

Use UNLOAD ([Section 3.24, "unload"](#)) to delete the subkey and to unlock the registry data file *filename*.

3.17. local_machine (Attribute [get])

Returns the handle of the root key HKEY_LOCAL_MACHINE. This handle is maintained by the operating system, it can not be changed.

3.18. open

Opens a named subkey with the specified access rights and returns its handle. When the programmer is done with the handle it should be closed using the close () ([Section 3.3, “close”](#)) method.

Note: The default for the access argument is ALL access. As Microsoft has tightened up the security in its operating systems, it has made access to the registry more restrictive than it was when the **WindowsRegistry** class was first introduced. Opening a registry key with more access rights than the user running the Rexx program has will result in failure. Best practice is to open a key with the least rights needed for the operation being performed.

For instance, in a Rexx program where the function is to read the values of a single key, the key should be opened with just the INQUIRE right. This is not only less likely to fail if the program user is not an Administrator, but is more secure in every case.

Arguments

The two arguments are:

parentHandle [optional]

A handle to the open parent key. If this argument is omitted then the current_key ([Section 3.6, “current_key \(Attribute \[get\]\)”](#)) attribute is used.

subkey [optional]

The name of the subkey to be opened. If this argument is omitted or the empty string, a new handle to the key identified by *parentHandle* is opened.

subkey [optional]

A string consisting of one or more of the following key words. The keywords are not case sensitive. The default is the ALL keyword.

ALL

Opens the key with all possible access. Although this is the default, as discussed above some forethought should be given to using this access.

WRITE

Combines the rights to create subkeys, set key values, and to read a key's access rights.

READ

Combines the rights to query key values, enumerate subkeys, read keys access rights, and the notify right. Note that READ access and EXECUTE access are exactly the same.

QUERY

Combines the right to query values of a registry key (specified by the INQUIRE keyword here,) with the right to enumerate subkeys.

INQUIRE

Required to query the values of a registry key.

ENUMERATE

Required to enumerate the subkeys of a registry key.

SET

Required to create, delete, or set a registry value.

DELETE

Exactly equivalent to SET access. The keyword is a convenience to make programs more readable.

CREATE

Required to create a subkey of a registry key.

NOTIFY

Required to request change notifications for a registry key or for subkeys of a registry key.

EXECUTE

Exactly equivalent to READ access.

LINK

The Microsoft documentation states that this right is reserved for system use. The keyword is listed here simply because it was documented in previous versions of ooRexx and Object Rexx. The programmer is advised not to use it.

Return

A handle to the opened key on success, otherwise 0. If the key was opened correctly, the value of the `current_key` ([Section 3.6, “current_key \(Attribute \[get\]\)”](#)) attribute is set to this handle. If the method fails, **current_key** is left unchanged.

3.19. query

Retrieves information about a given key in a compound variable. The values returned are *class* (class name), *subkeys* (number of subkeys) *values* (number of value entries), *date* and *time* of last modification. If *key_handle* is omitted, CURRENT_KEY is queried. Example:

Example 3.6. WindowsRegistry class - query method

```

myquery. = rg~query(objectrexxkey)
say "class="myquery.class "at" myquery.date
say "subkeys="myquery.subkeys "values="myquery.values
  
```

3.20. replace

Replaces the backup file of a key or subkey with a new file. Key must be an immediate descendant of HKEY_LOCAL_MACHINE or HKEY_USERS. If *key_handle* is omitted, the backup file of CURRENT_KEY is replaced. The values in the new file become active when the system is restarted. If *subkeyname* is omitted, the key and all its subkeys will be replaced.

3.21. restore

Restores a key from a file. If *key_handle* is omitted, CURRENT_KEY is restored. Example:

```
rg~restore(objectrexxkey, "\objrexx\orexx")
```

The VOLATILE keyword creates a new memory-only set of registry information that is valid only until the system is restarted.

3.22. save

Saves the entries of a given key into a file. If *key_handle* is omitted, CURRENT_KEY is saved. Example:

```
rg~SAVE(objectrexxkey, "\objrexx\orexx")
```

On a FAT system, do not use a file extension in *filename*.

3.23. setValue

Sets a named value of a given key. If *name* is blank or omitted, the default value is set.

Example 3.7. WindowsRegistry class - setValue method

```
rg~SETVALUE(objectrexxkey, , "My default", "NORMAL")
rg~SETVALUE(objectrexxkey, "Product_Name", "Object Rexx")
rg~SETVALUE(objectrexxkey, "VERSION", "1.0")
```

3.24. unload

Removes a named subkey (created with LOAD ([Section 3.16](#), “load”)) and its dependents from the registry, but does not modify the file containing the registry information. If *key_handle* is omitted, the subkey under CURRENT_KEY is unloaded. Unload also unlocks the registry information file.

3.25. users (Attribute [get])

Returns the handle of the root key HKEY_USERS. This handle is maintained by the operating system and can not be changed.

The WindowsEventLog Class

The **WindowsEventLog** class provides functionality to interact with the Windows system event log.

The WindowsEventLog class is not a built-in class. It is defined in the file **winSystem.cls**. To use the class, place a **::requires** statement in the program file:

```
::requires "winSystem.cls"
```

A sample program **eventlog.rex** is provided in the **samples\oodialog\winsystem** directory.

Methods:

The WindowsEventLog class implements the class and instance methods listed in the following table.

Table 4.1. WindowsEventLog Methods

Method	Category
new (Section 4.2 , “ new (Class method) ”)	Class method
events (Section 4.6 , “ events (Attribute) ”)	Attribute
minimumReadBuffer (Section 4.5 , “ minimumReadBuffer (Attribute) ”)	Attribute
minimumReadMin (Section 4.3 , “ minimumReadMin (Attribute) ”)	Attribute
minimumReadMax (Section 4.3 , “ minimumReadMin (Attribute) ”)	Attribute
clear (Section 4.12 , “ clear ”)	Instance method
close (Section 4.8 , “ close ”)	Instance method
getFirst (Section 4.19 , “ getFirst ”)	Instance method
getLast (Section 4.18 , “ getLast ”)	Instance method
getLogNames (Section 4.17 , “ getLogNames ”)	Instance method
getNumber (Section 4.16 , “ getNumber ”)	Instance method
isFull (Section 4.15 , “ isFull ”)	Instance method
minimumRead (Section 4.13 , “ minimumRead ”)	Instance method
minimumRead= (Section 4.14 , “ minimumRead= ”)	Instance method
open (Section 4.7 , “ open ”)	Instance method
Deprecated read (Section 4.9 , “ read (deprecated) ”)	Deprecated instance method
readRecords (Section 4.10 , “ readRecords ”)	Instance method
write (Section 4.11 , “ write ”)	Instance method

4.1. Using WindowsEventLog

In Windows the Event Log service provides a central facility for both the operating system and applications to log important events. The primary purpose for logging an event is to give administrators a way to determine the cause of errors and to prevent future errors. The Event Log service provides several standard logs: Application, Security, and System. The service also allows for applications to register and create Custom logs. Each event is logged as a single event log record in a single log.

The ooRexx **WindowsEventLog** class has methods that allow the programmer to query, read from, write to, back up, and clear event logs. The class can access logs on both the local machine and on remote machines accessed through the network. Full access to any log is governed by the security settings of the system. Therefore an ooRexx program that interacts with the Event Log service will be restricted to the privilege level of the user running the program.

The Event Log service uses information stored registry. This information controls how the service operates. The following list discusses some of the event logging elements to help the programmer better understand the methods and method arguments of the **WindowsEventLog** class:

Eventlog key

The Eventlog key is the key in the registry where all information for the Event Log service is stored. There are several subkeys under the EventLog key. Each subkey names an event *log*. The following shows the structure of the Eventlog key. The *Application*, *Security* and *System* subkeys below name the standard logs provided by the system. The actual name(s) and the number of *Custom logs* are dependent on the system.

```
HKEY_LOCAL_MACHINE
  System
    CurrentControlSet
      Services
        EventLog
          Application
          Security
          System
          CustomLog
```

Server

Many of **WindowsEventLog** instance methods have a *server* argument. This argument identifies which machine contains the desired event log. The argument is always optional, with the default server being the local machine. In all cases, using the empty string is the same as omitting the argument.

To work with a log on a remote system, the server name must be in Universal Naming Convention (UNC) format. For instance, `\\0sprey`.

Note that if there is an open ([Opened event log](#)) , the *server* argument is ignored.

Event Source

The *event source* is the name of the software or driver that logs the event. Event source names are usually the name of the application, or a component of the application if the application is large, or the driver name. Applications normally use the Application log, while drivers normally use the System log. Event source names are stored in the registry as subkeys of the log they are used in. Take the following registry example:

```
HKEY_LOCAL_MACHINE
  System
    CurrentControlSet
      Services
        EventLog
          Application
            WinApp1
            LoadPerf
          Security
            Security
          System
            Dhcp
            atapi
```

WinApp1, *LoadPerf*, *Security*, *Dhcp*, and *atapi* are all event sources.

Like the server ([Server](#)) argument, many of the WindowsEventLog instance methods have a *source* argument. This argument specifies the event source and therefore determines exactly which event log is used. The argument is always optional, the default is Application, and the empty string is the same as omitting the argument. In the same manner as the server argument, if there is an open event log ([Opened event log](#)), the *source* argument is ignored.

Note that if the Event Log service can not find the event source name in the registry, then the service also uses Application for the source.

When opening, querying, or reading event logs, using an event source name is no different than using the log name itself. For the above registry example, using:

```
eventLog-open( , "WinApp1")
```

or:

```
eventLog-open( , "LoadPerf")
```

is exactly the same as:

```
eventLog-open( , "Application")
```

However, when writing to an event log, the event source is included as part of the event log record. Therefore:

```
eventLog-open( , "WinApp1")
```

produces a different result than using:

```
eventLog-open( , "LoadPerf")
```

Although both event records will be written to the System log, the records will show the event source as WinApp1 in the first record and LoadPerf for the source in the second record.

Event Log Record

Each event is stored in an event log as a single record. The information in the record includes things like: time, type, category, record number, etc.. Each record contains the same fields, although some fields, like the binary data field, are not always filled in.

Each record has a record number. The first record written to a log is number 1 and records are then written consecutively. This makes the record with the lowest record number the oldest record. Likewise the highest record number makes that record the youngest record. The user can set a property for an event log to overwrite records when the maximum log size is reached. Because of this, the oldest record is not always record number 1. The `getFirst()` ([Section 4.19, "getFirst"](#)) and `getLast()` ([Section 4.18, "getLast"](#)) methods can be used to get the absolute record numbers of the oldest and youngest records.

Record numbers can be used in the `readRecords()` ([Section 4.10, "readRecords"](#)) method to read portions of the event log rather than the entire log.

When the `readRecords()` ([Section 4.10, "readRecords"](#)) method reads a record it converts the information in the record to a string with a defined format that makes it easy to parse. The parts (fields) of the string are as follows, in order:

Table 4.2. Event Record Fields

Field	Description	Format
type	The event type (<i>Event Type</i>)	Single word
date	The date the event was written	Single word
time	The time the event was written	Single word
source	The event source (<i>Event Source</i>)	Enclosed in single quotes
id	The event ID (<i>Event ID</i>)	Single word
userID	The user ID, if applicable	Single word
computer	The machine generating the event	Single word
description	A description of the event	Enclosed in single quotes
data	Binary data associated with the event	Enclosed in single quotes

Assuming that *rec* is the event record string, the following shows how to parse the string into its component fields:

```
parse var rec type date time "" source "" id userID computer "" description "" ""
data ""
```

Event Type

Each event recorded in an event log is a single type. There are five types of events that can be logged. Each event type has well-defined common data and some optional data that is specific to the event. When an event is logged the event type is included.

When the **WindowsEventLog** instance reads a record, the event type is indicated by a keyword. When the programmer writes to the event log using a **WindowsEventLog** object, she specifies the event type with its numeric value. The following table contains information on the five event types and shows the event type keywords and numeric values.

Table 4.3. Event Types

Type	Description	Keyword	Value
Error	An event that indicates a significant problem such as loss of data or loss of functionality. For example, if a service fails to load during startup, an Error event is logged.	Error	1 (0x01)
Warning	An event that is not necessarily significant, but may indicate a possible future problem. For example, when disk space is low, a Warning event is logged. If an application can recover from an event without loss of functionality or data, it can generally classify the event as a warning event.	Warning	2 (0x02)
Information	An event that describes the successful operation of an application, driver, or service. For example, when a network driver loads successfully, it may be appropriate to log an Information event. Note that it is generally inappropriate for a desktop application to log each time it starts.	Information	4 (0x04)

Type	Description	Keyword	Value
Information*	* The Windows API allows the numeric value of 0. This is not a separate event type, but rather a mapping of 0 to the Information event type. The WindowsEventLog also allows the use of 0 for the numeric value of an event type and maps it to Information.	Information	0 (0x00)
Success Audit	An event that records an audited security access attempt that is successful. For example, a user's successful attempt to log on to the system is logged as a Success Audit event.	Success	8 (0x08)
Failure Audit	An event that records an audited security access attempt that fails. For example, if a user tries to access a network drive and fails, the attempt is logged as a Failure Audit event.	Failure	16 (0x10)

Event ID

The event identifier value is specific to the event source for the event. It is used with source name to locate a description string in the message file for the event source.

Opened event log

When an event log has been opened using the `open()` ([Section 4.7, “open”](#)) method, that opened log is always used until it has been closed. The log can be closed using the `close()` ([Section 4.8, “close”](#)) method, or by another call to the `open()` method. This means that if there is an open log, the *server* and *source* arguments are **always** ignored. The only exception to this is the `write()` ([Section 4.11, “write”](#)) method. Each time a record is written to a log, the log is specifically opened for writing and then closed.

Note that when there is not an open event log, then all the instance methods behave as the `write()` method. That is, methods like `readRecords()` ([Section 4.10, “readRecords”](#)), `isFull()` ([Section 4.15, “isFull”](#)), etc., will open the log specified in the method call and then explicitly close the log before returning.

Event Category

Categories are used to organize events so that an event viewer can filter them. Each event source ([Event Source](#)) can define its own numbered categories and the text strings to which they are mapped.

The categories must be numbered consecutively, beginning with the number 1. The categories themselves are defined in a message file and the category number maps to a text string in the message file.

4.2. new (Class method)

Creates an instance of the `WindowsEventLog` class.

4.3. minimumReadMin (Attribute)

The programmer can set the size ([Section 4.14, “minimumRead=”](#)) of the minimum read buffer, within limits. `minimumReadMin` is the lowest acceptable size of the minimum read buffer.

~**minimumReadMin=** (set minimumReadMin)

minimumReadMin= is a private method, not intended to be changed by the programmer.

~**minimumReadMin** (get minimumReadMin)

The minimum number of kilobytes that the minimum read buffer can be set to.

Example:

The use of the attribute is straight-forward.

Example 4.1. WindowsEventLog class - minimumRead method

```
eventLog = .WindowsEventLog~new
say "Smallest possible read buffer is" eventLog~minimumReadMin "kilobytes"

::requires 'winSystem.cls'

/* Output might be:

Smallest possible read buffer is 16 kilobytes

*/
```

4.4. minimumReadMax (Attribute)

The programmer can set the size ([Section 4.14](#), “*minimumRead=*”) of the minimum read buffer, within limits. The **minimumReadMax** value is the largest acceptable size for the minimum read buffer.

~**minimumReadMax=** (set minimumReadMax)

minimumReadMax= is a private method, not intended to be changed by the programmer.

~**minimumReadMax** (get minimumReadMax)

The maximum number of kilobytes that the minimum read buffer can be set to.

Example:

This example displays the maximum size the programmer can set the minimum read buffer to.

Example 4.2. WindowsEventLog class - minimumReadMax method

```
eventLog = .WindowsEventLog~new
say "Largest possible minimum read buffer is" eventLog~minimumReadMax "kilobytes"

::requires 'winSystem.cls'

/* Output might be:

Largest possible minimum read buffer is 256 kilobytes

*/
```

4.5. minimumReadBuffer (Attribute)

Returns the current size of the minimum read buffer in bytes. The programmer can adjust the size ([Section 4.14, “minimumRead=”](#)) of the minimum read buffer. The value of this attribute reflects that size.

~minimumReadBuffer= (set minimumReadBuffer)

minimumReadBuffer= is a private method, not intended to be changed by the programmer. The programmer changes the size of the buffer using the **minimumRead=** ([Section 4.14, “minimumRead=”](#)) method.

~minimumReadBuffer (get minimumReadBuffer)

The current size in bytes of the minimum read buffer.

Example:

This example displays the size of the minimum read buffer when a new `WindowsEventLog` object is created and then displays the size after the programmer has changed the minimum.

Example 4.3. `WindowsEventLog` class - `minimumReadBuffer` method

```
eventLog = .WindowsEventLog~new
say "Current size of the minimum read buffer is" eventLog~minimumReadBuffer "bytes"

eventLog~minimumRead = 64
say "Adjusted size of the minimum read buffer to" eventLog~minimumReadBuffer "bytes"

::requires 'winSystem.cls'

/* Output might be:

Current size of the minimum read buffer is 16384 bytes
Adjusted size of the minimum read buffer to 65536 bytes

*/
```

4.6. events (Attribute)

The **events** attribute is an array that holds the event log records that are read from the event log during a call to `readRecords()` ([Section 4.10, “readRecords”](#)). The array is empty if no call to **readRecords()** has been made. Each time **readRecords()** is called the array is first emptied.

Each index in the array holds one event record in the form of a string with a fixed format ([Event Log Record](#)).

~events= (set events)

events= is a private method, not intended to be changed by the programmer.

~events (get events)

Returns the array holding the event log records from the last `readRecords()` ([Section 4.10, “readRecords”](#)) call. The array will be empty if no call to **readRecords()** has been made.

Example:

This example displays the number of event log records that were read from the System log.

Example 4.4. `WindowsEventLog` class - `events` method

```
eventLog = .WindowsEventLog~new
```

```

    if eventLog~readRecords("BACKWARDS", , "System") == 0 then do
        say 'The System log has' eventLog~events~items 'records'
    end

    ::requires 'winSystem.cls'

    /* Output might be:

    The System log has 1983 records

    */

```

4.7. open

Opens the specified event log. Once an event log is opened, other methods of the **WindowsEventLog** instance will use that opened log (*Opened event log*) until it has been closed (*Section 4.8, “close”*).

If an event log is already open, then it is first closed before the specified log is opened.

Arguments:

The arguments are:

server

Optional. The name of the server (*Server*) where the event log resides).

source

Optional. The event source (*Event Source*).

Return value:

This method returns 0 on success, and the operating system error code on failure.

Example:

The following two code snippets are equivalent. They both open the Application log on the local machine if they succeed:

Example 4.5. WindowsEventLog class - open method

```

eventLog1 = .WindowsEventLog~new
ret = eventLog1~open
if ret \== 0 then do
    say 'Failed to open the event log:'
    say '  Error' ret': 'SysGetErrorText(ret)
    ...
end

eventLog2 = .WindowsEventLog~new
ret = eventLog2~open( , "Application")
if ret \== 0 then do
    say 'Failed to open the event log'
    say '  Error' ret': 'SysGetErrorText(ret)
    ...
end

```

The following example opens the System log on SERVER01:

Example 4.6. WindowsEventLog class - open method

```
eventLog = .WindowsEventLog-new
ret = eventLog~open("\\SERVER01", "System")
if ret == 0 then do
  -- Do something with the event log
  ...
  eventLog~close
  ...
end
else do
  -- Handle the error in some way
  ...
end
```

4.8. close

Closes an open event log (*Opened event log*). If no log is open, this method does nothing.

Arguments:

There are no arguments.

Return value:

This method returns 0 on success. If there is an error closing the event log the operating system error code is returned. An error is highly unlikely.

Example:

The following code snippet opens the default event log (the Application log,) displays some information about the log, then closes the open log.

Example 4.7. WindowsEventLog class - close method

```
log = .WindowsEventLog-new

ret = log~open
if ret == 0 then do
  say " Total records:      " log~getNumber
  say " First record number" log~getFirst
  say " Last record number " log~getLast
  say " Log is full?       " log~isFull
  log~close
end

/* Output might be:

Total records:      1827
First record number 1
Last record number 1827
Log is full?       0

*/
```

4.9. read (deprecated)

Note

This method is deprecated. It is replaced by the functionally equivalent `readRecords()` ([Section 4.10, “readRecords”](#)) method. Do not use this method in new code. Try to migrate existing code to to the **`readRecords()`** method. This method may not exist in future versions of ooRexx.

4.10. readRecords

Reads the desired event records from the specified event log. Each record is stored in the `events` ([Section 4.6, “events \(Attribute\)”](#)) array. After a successful read, all records will be contained in the **`events`** array in the order there were read. Prior to starting the read operation the array is emptied.

Details:

This method will raise syntax errors if the *start* or *count* arguments are used incorrectly. These arguments, if used, must specify records actually contained in the event log. Use any combination of the `getFirst()` ([Section 4.19, “getFirst”](#)), `getLast()` ([Section 4.18, “getLast”](#)), or `getNumber()` ([Section 4.16, “getNumber”](#)) methods to determine the absolute record numbers contained in the log.

During a read operation, if a single event record is larger than the read buffer an execution error will be raised. The text of the error will read: An event log record is too large (*recordSize*) for the read buffer (*bufferSize*.) Where *recordSize* is the size of the record and *bufferSize* is the size of the read buffer at the time of the error.

The minimum size of the read buffer can be increased by using the `minimumRead=` ([Section 4.14, “minimumRead=”](#)) method. If this error occurred, the minimum read buffer should be set larger than the size of the offending record.

Note well: It seems inconceivable that the read buffer could be smaller than a single event record. The minimum possible size of the buffer is 16 KB and the average size of an event record is between 100 and 200 bytes. The ooRexx programmer should **not** worry about this. This unlikely possibility is simple documented for the sake of completeness.

Arguments:

The arguments are:

direction

Optional. The direction to read the from the event log, forwards or backwards. The default is to read forwards. If this argument is not omitted, it must be exactly one of the keywords, BACKWARDS or FORWARDS. Case is not significant.

server

Optional. The name of the server ([Server](#)) where the event log resides

source

Optional. The event source ([Event Source](#)).

start

Optional. The starting record number for the read operation. The start and the count arguments must be used together. Either both must be used or neither. If both arguments are omitted, the entire log is read. When both arguments are used, the read begins with the record number specified by *start* and reads in the direction specified for *count* records.

count

Optional. The count of records to be read during the read operation. The start and the count arguments must be used together. Either both must be used or neither. If both arguments are omitted, the entire log is read. When both arguments are specified, the read begins with the record number specified by *start* and reads in the direction specified for *count* records.

Return value:

This method returns 0 on success, and the operating system error code on failure.

Example:

This example reads the 5 most recent event records in the System event log and displays them to the console. (If there are less than 5 records in the log, then all the records are read.)

Example 4.8. WindowsEventLog class - readRecords method

```
log = .WindowsEventLog~new

startRec = log~getLast( , "System")
count = log~getNumber~min(5)

ret = log~readRecords("BACKWARDS", , "System", startRec, count)

if ret == 0 then do
    c = displayRecords(log~events)
    say 'Displayed' c 'records'
end
else do
    say "Error reading the System event log rc:" ret "-" SysGetErrorText(ret)
end

::requires 'winSystem.cls'

/* Routine to display the event log records */
::routine displayRecords
    use strict arg records

    do record over records
        say "=====
        parse var record type date time "" sourcename"" id userid computer "" string
        "" "" data ""
        say 'Type      : 'type
        say 'Date      : 'date
        say 'Time      : 'time
        say 'Source    : 'sourcename
        say 'ID        : 'id
        say 'UserId    : 'userid
        say 'Computer  : 'computer
        say 'Detail    : 'string
        say 'Data      : 'data
```

```

end
say "=====
return records~items

/* The output (shortened to 2 records) might be:

=====
Type      : Information
Date      : 02/14/09

*/

```

4.11. write

Description

Arguments:

The arguments are:

srvr

Optional. The name of the server ([Server](#)) where the event log resides

src

Optional. The event source ([Event Source](#)).

type

Optional. The event type ([Event Type](#)) for the record. The default is the *Error* (1) event type. When used, this argument must be the numeric value of a valid event type ([Event Type](#)).

category

Optional. The event category (*Event Category*) for the record. The default is 0, which is the same as no category (none.)

id

Optional. The event identifier (*Event ID*) for the record.. The default is 0.

data

Optional. The binary data for the record. The default is none. This is binary information specific to the event being logged and to the source that generated the entry. It could for example be the contents of the processor registers when a device driver got an error, a dump of an invalid packet that was received from the network, etc..

string

Optional. The default is no string. This last argument can be repeated any number of times. Each additional argument is a string used as a substitution string in the description string.

The event identifier (*Event ID*) together with the event source(*Event Source*) name identify a description string contained in a message file that describes the event in more detail. The description string can contain substitution place holders. The substitution strings named by this argument are used to replace the substitution place holders in the description string.

Return value:

This method returns 0 on success, and the operating system error code on failure.

Example:

This example writes some fictitious data to an event log.

Example 4.9. WindowsEventLog class - write method

```
log = .WindowsEventLog~new

source      = "MyApplication"
type        = 4  -- Information
category    = 22
id          = 33
binaryData  = "01 1a ff 4b 0C"x

ret = log-write( , source, type, category, id, binaryData, "String1", "String2")
if ret == 0 then
  say "Record" source "successfully written"
else
  say "Error writing record" source "rc:" ret ":" SysGetErrorText(ret)

::requires 'winSystem.cls'
```

4.12. clear

Clears (removes) all event records from the log. Optionally will back up the log first. When the optional backup file name is supplied and for some reason the back up fails, then the event records are not cleared.

Arguments:

The arguments are:

srvr

Optional. The name of the server ([Server](#)) where the event log resides

src

Optional. The event source ([Event Source](#)).

backupFileName

Optional. The path name to a back up file. If this argument is specified, the event log is first backed up before it is cleared. If the back up fails, the log is not cleared. The back will fail if the file name specified already exists.

The back up file will be created on the system that the event log file itself is on. This means that if an event log on a remote system is specified, the log will be created on that remote system. The file name must therefore be a valid file name on the remote system.

If the file name does not contain an extension, the the normal extension for event log back ups, **.evt**, will be used.

Return value:

This method returns 0 on success, and the operating system error code on failure.

Example:

This example backs up the Application event log on the remote Eagle system and then clears the log. If the back up fails, the log will not be cleared. The back up file will be named eagle_application.evt and will be located on the Eagle system, not on the local machine.

Example 4.10. WindowsEventLog class - clear method

```
log = .WindowsEventLog~new

ret = log-open("\\Eagle", "Application")
if ret == 0 then do
    ret = log-clear( , , "C:\eagle_application")
    if ret == 0 then do
        say 'Backed up the Application event log on Eagle to:'
        say '  C:\eagle_application.evt on the Eagle system.'
    end
else do
    say 'Failure backing up event log:' ret ":" SysGetErrorText(ret)
end
end

::requires 'winSystem.cls'
```

4.13. minimumRead

Determines the current minimum size, in kilobytes, of the buffer used to read ([Section 4.10](#), [“readRecords”](#)) event log records. The minimum size of this buffer can be adjusted ([Section 4.14](#), [“minimumRead=”](#)) by the programmer.

Arguments:

There are no arguments to this method.

Return value:

The size in kilobytes of the minimum read buffer. For example if the minimum buffer size is 32,768, this method will return 32. (32 KB.)

Example:

This example displays the current value of the minimum read buffer size.

Example 4.11. WindowsEventLog class - minimumRead method

```
log = .WindowsEventLog~new
say 'Current minimum size of the read buffer is:' log~minimumRead "KB"

::requires 'winSystem.cls'

/* Output might be:

Current minimum size of the read buffer is: 16 KB

*/
```

4.14. minimumRead=

Adjusts the minimum size of the read buffer in increments of 1024 bytes. **Note** that the programmer need not worry about the read buffer. This method is documented because it does exist and for the sake of the rare Rexx programmer that might need to change the minimum size of the read buffer.

The read buffer is used by the underlying implementation during the readRecords() ([Section 4.10, "readRecords"](#)) method only. During a read operation, the **WindowsEventLog** attempts to allocate a buffer that is big enough to read in all the records at once. The size of the buffer is guessed at by using the number of records in the event log. The size is constrained by a minimum ([Section 4.3, "minimumReadMin \(Attribute\)"](#)) and maximum ([Section 4.4, "minimumReadMax \(Attribute\)"](#)). The buffer will never be larger than the maximum and never smaller than the minimum. The maximum value is fixed. The minimum value can be adjusted by the programmer by this, the **minimumRead()** method.

In almost all cases, the size of the buffer will be set towards the maximum constraint and the minimum constraint will not come into play at all. There is only one circumstance where the Rexx programmer would need to change the minimum constraint, which is this:

The Windows Event Log Service will only place whole records into the buffer. If a record is bigger in size than the buffer, the record can not be read and an execution error will be raised by the **WindowsEventLog** object. In this case the minimum constraint for the buffer size would need to be set to a size bigger than the record size. The text of the error message lists both the record size and the buffer size. To read the record, the programmer would set the minimum constraint larger than the record size.

Again, it *must be stressed* that the above scenario is extremely unlikely.

Arguments:

The single argument is:

sizeKB

The minimum size to allocate the read buffer, in kilobytes.

Return value:

There is no return.

Example:

This method is straight forward to use:

Example 4.12. WindowsEventLog class - minimumRead= method

```
log = .WindowsEventLog~new
log~minimumRead = 64
say 'Current minimum read is' log~minimumRead 'KB.'

::requires 'winSystem.cls'

/* Output might be:

Current minimum size of the read buffer is: 64 KB

*/
```

4.15. isFull

Determines if the event log is full.

Arguments:

The arguments are:

server

Optional. The server ([Server](#)) where the event log resides.

source

Optional. The event source ([Event Source](#)).

Return value:

The method returns **.true** or **.false**. True if the event log is full, otherwise false.

Example:

This example is a snippet of code from an application that monitors the system log. When the log gets full, the log is backed up and cleared.

Example 4.13. WindowsEventLog class - isFull method

```
::routine checkLog
use strict arg sysLog, monitor

if sysLog~isFull then do
  success = monitor~backupLog(sysLog)
  if \ success then monitor~notifyAdmin
end
return success
```

4.16. getNumber

Determines the number of records in the event log.

Arguments:

The arguments are:

server

Optional. The server ([Server](#)) where the event log resides.

source

Optional. The event source ([Event Source](#)).

Return value:

On success, the count of event records in the log. On error, the return is the negated system error code.

Example:

This example opens the system log on the Osprey server. It then checks that there are at least 10 records before reading the log:

Example 4.14. WindowsEventLog class - getNumber method

```
log = .WindowsEventLog~new
log~open("\\Osprey", "System")
if log~getNumber > 10 then do
  log~readRecords
  say 'Read' log~events~items 'records.'
end

::requires 'winSystem.cls'
```

4.17. getLogNames

Obtains a list of all the event log names on the current system.

Arguments:

The single argument is:

names

An array object. On return the array will contain the names of the event logs on the current system. This will include any custom logs, if there are any. The array is emptied before the names are added. If an error happens, the array will be empty.

Return value:

This method returns 0 on success, and the operating system error code on failure.

Example:

This example displays the names of all the event logs on the current system.

Example 4.15. WindowsEventLog class - getLogNames method

```
logNames = .array~new
ret = log~getLogNames(logNames)

if ret == 0 then do name over logNames
  say "Log:" name
end

::requires 'winSystem.cls'
```

```

/* Output might be:

Log: Application
Log: Internet Explorer
Log: Security
Log: System

*/

```

4.18. getLast

Determines the absolute record number of the last record in the event log.

Arguments:

The arguments are:

server

Optional. The server ([Server](#)) where the event log resides.

source

Optional. The event source ([Event Source](#)).

Return value:

On success, the record number of the last (most recently written) event record. On error, the return is the negated system error code.

Example:

This example displays the last record written to application log.

Example 4.16. WindowsEventLog class - getLast method

```

log = .WindowsEventLog~new~~open
log~readRecords( , , , log~getLast, 1)
rec = log~events[1]
if rec \== .nil then do

    parse var rec type date time "" src"" id user computer "" string "" "" data
    ""
    say 'Type      : 'type
    say 'Date      : 'date
    say 'Time      : 'time
    say 'Source    : 'src
    say 'ID        : 'id
    say 'UserId    : 'user
    say 'Computer  : 'computer
    say 'Detail    : 'string
    say 'Data      : 'data
end

::requires 'winSystem.cls'

/* Output might be:

Type      : Error
Date      : 02/14/09
Time      : 16:55:08
Source    : Windows Search Service
ID        : 3083

```

```

UserId    : N/A
Computer  : OSPREY
Detail    : The protocol handler Search.Mapi2Handler.1 cannot be loaded. Error
           description: Class not registered.
Data      :

*/

```

4.19. getFirst

Determines the absolute record number of the first record in the event log.

Arguments:

The arguments are:

server

Optional. The server ([Server](#)) where the event log resides.

source

Optional. The event source ([Event Source](#)).

Return value:

On success, the first record number in the event log. On error, the return is the negated system error code.

Example:

This example displays the first record written to the application log.

It is somewhat interesting to note that this first record was written right after the operating system had been installed, prior to the computer being added to a work group and given the Osprey name. This can be seen when the record is displayed, the Computer field is MACHINENAME.

Example 4.17. WindowsEventLog class - getFirst method

```

log = .WindowsEventLog~new~open("\\0sprey", "System")
log~readRecords( , , , log~getFirst, 1)
rec = log~events[1]
if rec \== .nil then do

    parse var rec type date time "" src"" id user computer "" string "" "" data
    ""
    say 'Type      : 'type
    say 'Date      : 'date
    say 'Time      : 'time
    say 'Source    : 'src
    say 'ID        : 'id
    say 'UserId    : 'user
    say 'Computer  : 'computer
    say 'Detail    : 'string
    say 'Data      : 'data
end

::requires 'winSystem.cls'

/* Output might be:

Type      : Information
Date      : 08/16/08

```

```
Time      : 04:27:01
Source    : EventLog
ID        : 6009
UserId    : N/A
Computer  : MACHINENAME
Detail    : 5.02. 3790 Service Pack 1 Multiprocessor Free
Data      :
```

```
*/
```

The WindowManager Class

The WindowManager class provides methods to query, manipulate, and interact with windows on your desktop. Currently, this class is specifically for the Windows operating system and is not available on other operating systems.

The WindowManager class is not a built-in class, it is defined in the file `winSystem.cls`. To use the class, add a `::requires` statement to the program file:

```
::requires "winSystem.cls"
```

Methods the WindowManager Class Defines

- `desktopWindow`
- `find`
- `foregroundWindow`
- `windowAtPosition`
- `consoleTitle`
- `consoleTitle=`
- `sendTextToWindow`
- `pushButtonInWindow`
- `processWindowCommand`
- `broadcastSettingChanged`

5.1. desktopWindow

Returns an instance of the WindowObject ([Chapter 6, The WindowObject Class](#)) class that represents the Desktop window. The Desktop window is the parent of all top-level windows and therefore the ancestor of every window on the system. If some error happens, `.nil` is returned. (This is extremely unlikely.)

5.2. find

Searches for a top-level window (not a child window) on your desktop with the specified *title*.

If this window already exists, an instance of the WindowObject class is returned. Otherwise, `.Nil` is returned.

5.3. foregroundWindow

Returns an instance of the WindowObject class that is associated with the current foreground window.

5.4. windowAtPosition

Returns an instance of the WindowObject class that is associated with the window at the specified position (x,y). The coordinates are specified in screen pixels. This method does not retrieve hidden or disabled windows. If you are interested in a particular child window, use method childAtPosition ([Section 6.23, “childAtPosition”](#)).

5.5. consoleTitle

Returns the title of the current console.

5.6. consoleTitle=

Sets the title of the current console.

5.7. sendTextToWindow

Sends a case-sensitive *text* to the window with the specified *title*..

5.8. pushButtonInWindow

Selects the button with label *text* in the window with the specified *title*. If the button's label contains a mnemonic (underscored letter), you must specify an ampersand (&) in front of it. You can also use this method to select radio buttons and to check or uncheck check boxes.

Example:

```
winmgr~pushButtonInWindow("Testwindow","List &Employees")
```

5.9. processMenuCommand

Selects an item of the menu or submenu of the specified window *title*. You can specify as many submenus as necessary to get to the required item.

5.10. broadcastSettingChanged

Causes the Windows operating system to send a message, (the WM_SETTINGCHANGE message,) to every top-level window on the Desktop informing them that a system-wide setting has changed. Well-written applications will then reload any system settings that they use.

An example of one use for this might be an installer program setting an environment variable, such as the PATH. Then a call to broadcastSettingChanged would cause all open applications to update their reference to the environment, without the necessity of a reboot.

There are two variations of calling this method. When called with no arguments, the message is broadcast and returns immediately. When called with the time out parameter, the message is broadcast and does not return until every window on the Desktop has acknowledged the message, or timed out.

The problem with using a time out and waiting for acknowledgment is that, if a window is not responding, or several windows are slow to respond, it may take a very long time to return. The problem with not using a time out and returning immediately is that the caller will have no way of knowing when every window has received the message. Generally this is not a problem, but it is up to the programmer to decide how she wants to use this method.

The time out value is specified in milliseconds. For each window, the operating system will wait up to the time out for a response before going on to the next window. Typically a time out value of 5000 (5 seconds) is used, and this is the default.

The single optional argument is:

timeOut

The time, in milliseconds, to wait for each window to acknowledge it received the setting changed message. Specifying 0 or a negative number will cause the default time out of 5000 to be used. (5000 is a typical value used by applications.)

Return value:

0

The setting changed message was broadcast successfully. If no time out argument was used, then this is all it means. If a time out value was used, then all top-level windows have acknowledged receiving the message.

-1

The setting changed message was broadcast, but one or more windows timed out. This return can only happen when the time out parameter is used.

-x

A number less than -1 indicates a system error occurred. This value is the negation of the system error code. I.e., if the return is -1400, the system error code was 1400. System error codes can be looked up in the MSDN library or the Windows Platform SDK. Microsoft makes these references available on the Internet.

+x

A number greater than 0 would be a window result of broadcasting the setting changed message and would not be an error. It is unlikely that this would occur.

Example:

```
ret = winmgr~broadcastSettingChanged(1000)
```

The WindowObject Class

The WindowObject class provides methods to query, manipulate, and interact with a particular window or one of its child windows.

Access to the WindowObject class requires that the following directive appear in the Rexx program.

```
::requires 'winSystem.cls'
```

Note. Prior to the release of ooRexx 4.0.0, the WindowsObject class was implemented using the original external function API. That API required that the external functions be registered with the interpreter. For the most part this was done transparently to the Rexx programmer. However, with the WindowsObject class there was one scenario where the registration was not done and prior documentation provided a work around.

Starting with ooRexx 4.0.0, that work around is not needed. There no longer is any need for the programmer to register external functions at all. Requiring **winSystem.cls** is all that is needed from ooRexx 4.0.0 and on. Disregard the previous documentation concerning external functions.

Methods the WindowObject Class Defines

- assocWindow
- childAtPosition
- coordinates
- disable
- enable
- enumerateChildren
- findChild
- first
- firstChild
- focusItem
- focusNextItem
- focusPreviousItem
- getStyle
- handle
- hide
- id
- isMenu
- last
- maximize

- menu
- minimize
- moveTo
- next
- owner
- previous
- processMenuCommand
- pushButton
- resize
- restore
- sendChar
- sendCommand
- sendKey
- sendKeyDown
- sendKeyUp
- sendMenuCommand
- sendMessage
- sendMouseClicked
- sendSyscommand
- sendText
- state
- systemMenu
- title
- title=
- toForeground
- wclass

6.1. assocWindow

Assigns a new window *handle* to the WindowObject instance.

6.2. handle

Returns the handle of the associated window.

6.3. title

Returns the title of the window.

6.4. title=

Sets a new title for the window.

6.5. wclass

Returns the class of the window associated with the WindowObject instance.

6.6. id

Returns the numeric ID of the window.

6.7. coordinates

Returns the upper left and the lower right corner positions of the window in the format "left,top,right,bottom".

6.8. state

Returns information about the window state. The returned state can contain one or more of the following constants:

- "Enabled" or "Disabled"
- "Visible" or "Invisible"
- "Zoomed" or "Minimized"
- "Foreground"

6.9. getStyle

Returns the style and extended style flags of the window. This method is intended for use by programmers that have some knowledge of the Windows API and would not be much use to Rexx programmers that do not have any understanding of that API.

The styles are returned in a string of two words. The first word is the window style and the second word is the extend window style. Each word is in the format: **0xAAAAAAAA** where A represents any hexadecimal digit. If an error happens, the numerical system error code is returned instead of a string with two words.

Example 6.1. getStyle

```
-- This function will return an array with all matching windows.  An empty array
-- signals no match.
windows = fuzzyFindWindows(deskTop, text)

if windows~items > 0 then do wnd over windows
  say 'Found this window.'
  say '  Title:    ' wnd~title
  say '  Class:    ' wnd~wClass
  say '  Position:' wnd~coordinates
  say '  Styles:   ' wnd~getStyle
  say
end

/* Output might be:

Found this window.
  Title:    GetMenuState Function - MSDN Library - Microsoft Document Explorer
  Class:    wndclass_desked_gsk
  Position: 0,0,1152,800
  Styles:   0x16cf0000 0xc0040900

Found this window.
  Title:    C:\work.ooRexx\3.x\main
  Class:    ExploreWClass
  Position: 0,25,1150,804
  Styles:   0x16cf0000 0xc0000900

*/
```

6.10. restore

Activates and displays the associated window. If the window is minimized or maximized, it is restored to its original size and position.

6.11. hide

Hides the associated window and activates another window.

6.12. minimize

Minimizes the associated window and activates the next higher-level window.

6.13. maximize

Maximizes the associated window.

6.14. resize

Resizes the associated window to the specified width and height. The width and height are specified in screen coordinates.

6.15. enable

Enables the associated window if it was disabled.

6.16. disable

Disables the associated window.

6.17. moveTo

Moves the associated window to the specified position (x,y). Specify the new position in screen pixels.

6.18. toForeground

Makes the associated window the foreground window.

6.19. focusNextItem

Sets the input focus to the next child window of the associated window.

6.20. focusPreviousItem

Sets the input focus to the previous child window of the associated window.

6.21. focusItem

Sets the input focus to the child window associated with the specified WindowObject instance *wndObject*.

The following example sets the input focus to the last child window:

Example 6.2. focusItem

```

dlg = wndmgr~find("TestDialog")
if dlg \= .Nil then do
    fChild = dlg~firstChild
    lChild = fChild~last
    dlg~focusItem(lChild)
end
  
```

6.22. findChild

Returns an instance of the WindowObject class associated with the child window with the specified *label*. If the associated window does not own such a window, the .Nil object is returned.

6.23. childAtPosition

Returns an instance of the WindowObject class associated with the child window at the specified client position (x,y). The coordinates that are relative to the upper left corner of the associated window must be specified in screen pixels. To retrieve top-level windows, use method `windowAtPosition` ([Section 5.4, "windowAtPosition"](#)).

6.24. next

Returns an instance of the WindowObject class associated with the next window of the same level as the associated window. If the associated window is the last window of a level, the .Nil object is returned.

6.25. previous

Returns an instance of the WindowObject class associated with the previous window of the same level as the associated window. If the associated window is the first window of a level, the .Nil object is returned.

6.26. first

Returns an instance of the WindowObject class associated with the first window of the same level as the associated window.

6.27. last

Returns an instance of the WindowObject class associated with the last window of the same level as the associated window.

6.28. owner

Returns an instance of the WindowObject class associated with the window that owns the associated window (parent). If the associated window is a top-level window, the .Nil object is returned.

6.29. firstChild

Returns an instance of the WindowObject class associated with the first child window of the associated window. If no child window exists, the .NIL object is returned.

6.30. enumerateChildren

Returns a stem that stores information about the child windows of the associated window. "Stem.0" contains the number of child windows. The returned stem contains as many records as child windows. The first record is stored at "Stem.1" continued by increments of 1. Each record contains the following entries, where each entry starts with an exclamation mark (!):

!Handle

The handle of the window.

!Title

!Class

The window class.

!State

!Coordinates

!Children

1 if the window has child windows, 0 if it has none.

!Id

Example 6.3. enumerateChildren

```
wo = winmgr~find("TestDialog")
enum. = wo~enumerateChildren
do i = 1 to enum.0 /* number of children */
```

```

say "---"
say "Handle:" enum.i.!Handle
say "Title:" enum.i.!Title
say "Class:" enum.i.!Class
say "Id:" enum.i.!Id
say "Children:" enum.i.!Children
say "State:" enum.i.!State
say "Rect:" enum.i.!Coordinates
end

```

6.31. sendMessage

Sends a message to the associated window.

6.32. sendCommand

Sends a WM_COMMAND message to the associated window. WM_COMMAND is sent, for example, when a button is pressed, where *command* is the button ID.

6.33. sendMenuCommand

Selects the menu item *id* of the associated window. Method `idOf` ([Section 7.6, “idOf”](#)) returns the ID of a menu item.

6.34. sendMouseClicked

Simulates a mouse click event in the associated window.

Arguments:

The arguments are:

which

Specifies which mouse button is simulated. LEFT is the default.

kind

Selects the simulated mouse action. DBLCLK is the default.

x,y

Specifies the coordinates of the mouse click event, in screen coordinates, relative to the upper left corner of the window.

ext

Can be one or more of the following strings:

LEFTDOWN

Simulates the pressed left mouse button.

RIGHTDOWN

Simulates the pressed right mouse button.

MIDDLEDOWN

Simulates the pressed middle mouse button.

SHIFT

Simulates the pressed Shift key.

CONTROL

Simulates the pressed Control key.

6.35. sendSyscommand

Sends a `WM_SYSCOMMAND` message to the associated window. These messages are normally sent when the user selects a command in the Window menu.

Argument:

The only argument is:

command

One of the commands listed in the syntax diagram:

SIZE

Puts the window in size mode.

MOVE

Puts the window in move mode.

MINIMIZE

Minimizes the window.

MAXIMIZE

Maximizes the window.

NEXTWINDOW

Moves to the next window.

PREVWINDOW

Moves to the previous window.

CLOSE

Closes the window.

VSCROLL

Scrolls vertically.

HSCROLL

Scrolls horizontally.

ARRANGE

Arranges the window.

RESTORE

Restores the window to its normal position and size.

TASKLIST

Activates the Start menu.

SCREENSAVE

Executes the screen-saver application specified in the [boot] section of the SYSTEM.INI file.

CONTEXTHELP

Changes the cursor to a question mark with a pointer. If the user then clicks on a control in the dialog box, the control receives a WM_HELP message.

6.36. pushButton

Selects the button with the specified *label* within the associated window and sends the corresponding WM_COMMAND message. If the button's label contains a mnemonic (underscored letter), you must specify an ampersand (&) in front of it. You can also use this method to select radio buttons and check or uncheck check boxes.

6.37. sendKey

Sends all messages (CHAR, KEYDOWN, and KEYUP) that would be sent by pressing a specific key on the keyboard. Character keys (a to z) are not case-sensitive.

If the *alt* argument is 1, the Alt key flag is set, which is equal to pressing the specified key together with the Alt key.

The *Ext* argument must be 1 if the key is an extended key, such as a right Ctrl or a right Shift.

For a list of key names, refer to [Section 1.10, “Symbolic Names for Virtual Keys”](#).

6.38. sendChar

Sends a WM_CHAR message to the associated window. If the *alt* argument is 1, a pressed Alt key is simulated.

6.39. sendKeyDown

Sends a WM_KEYDOWN message to the associated window. The *ext* argument must be 1 if the key is an extended key, such as a right Ctrl or a right Shift.

For a list of key names, refer to [Section 1.10, “Symbolic Names for Virtual Keys”](#).

6.40. sendKeyUp

Sends a WM_KEYUP message to the associated window. The *ext* argument must be 1 if the key is an extended key, such as a right Ctrl or a right Shift.

For a list of key names, refer to [Section 1.10, “Symbolic Names for Virtual Keys”](#).

6.41. sendText

Sends a (case-sensitive) text to the associated window by sending a sequence of WM_CHAR, WM_KEYDOWN, and WM_KEYUP messages.

6.42. menu

Returns an instance of the MenuObject class that refers to the menu of the associated window.

6.43. systemMenu

Returns an instance of the MenuObject class that refers to the system menu of the associated window.

6.44. isMenu

Returns 1 if the associated window is a menu, otherwise 0.

6.45. processMenuCommand

Selects an item of the menu or submenu of the associated window. You can specify as many submenus as necessary to get to the required item.

The MenuObject Class

The MenuObject class provides methods to query, manipulate, and interact with the menu or submenu of a window.

Use of the MenuObjects requires that the following directive appear in the Rexx program.

```
::requires 'winSystem.cls'
```

Methods the MenuObject Class Defines

- findItem
- findSubMenu
- idOf
- isChecked
- isMenu
- isSubMenu
- isSeparator
- items
- processItem
- submenu
- textOf(id)
- textOf(position)

7.1. isMenu

Returns 1 if the associated window is a menu, otherwise 0.

7.2. isSubMenu

Returns **.true** if the menu item at the position specified is a submenu of this menu, otherwise **.false**. Menu items are zero-based, so the first menu item is at position 0.

7.3. isChecked

Returns **.true** if the menu item at the position specified is checked, otherwise **.false**. Menu items are zero-based, so the first menu item is at position 0. Submenus and separators can be checked.

This method can not be 100% reliable. Some applications do not set the check mark for a menu item until the menu is displayed. To be confident of the result, the programmer should first test how a specific application behaves.

7.4. isSeparator

Returns **.true** if the menu item at the position specified is a separator line, otherwise **.false**. Menu items are zero-based, so the first menu item is at position 0.

7.5. items

Returns the number of menu items contained in the associated menu.

7.6. idOf

Returns the ID of the menu item at the specified *position*, starting with 0.

7.7. textOf(position)

Returns the text of the menu item at the specified *position*, starting with 0. A mnemonic (underscored letter) is represented by a leading ampersand (&). If the menu item contains an accelerator, it is separated by a tab.

7.8. textOf(id)

Returns the text of menu item *id*. A mnemonic is represented by a leading ampersand (&). If the menu item contains an accelerator, it is separated by a tab.

7.9. submenu

Returns an instance of the MenuObject class that is associated with the submenu at the specified *position*, starting with 0. If no submenu exists at this position, the **.Nil** object is returned.

Example:

```
sub = menu~submenu(5)
if sub \= .Nil then do
  say "Items:" sub~items
end
```

7.10. findSubMenu

Returns an instance of the MenuObject class that is associated with the submenu with the specified *label*. If the associated menu does not contain such a submenu, the .Nil object is returned.

7.11. findItem

Returns the ID of the menu item *label*. If the specified label does not include an accelerator, the comparison excludes the accelerators of the menu items. If no menu item is found that matches the specified label, 0 is returned.

Example:

```
f = menu~findItem("&Tools" || "9"x || "Ctrl+T")
if f \= 0 then menu~processItem(f)
```

7.12. processItem

Selects the menu item *id*. This causes a WM_COMMAND to be sent to the window owning the menu.

OLE Automation

OLE (Object Linking and Embedding) automation is a subset of COM (Component Object Model). These technologies were first developed on Windows and are deeply embedded in the Windows operating system. Although COM is not tied to the Windows operating system, in practice it is not seen much on other operating systems. Because of this, the ooRexx classes supporting OLE Automation are currently Windows only classes.

8.1. Overview of OLE Automation

OLE (Object Linking and Embedding) is an implementation of COM (Component Object Model). OLE automation makes it possible for one application to manipulate objects implemented in another application, or to expose objects so they can be manipulated. ooRexx provides two classes, `OLEObject` ([Section 8.3, “The OLEObject Class”](#)) and `OLEVariant` ([Section 8.4, “The Windows OLEVariant Class”](#)) that allow the programmer to take advantage of this ability to manipulate objects that are exposed as OLE objects.

An automation client is an application that can manipulate exposed objects belonging to another application. An automation server is an application that exposes the objects. The `OLEObject` class enables Rexx to be an OLE automation client. In addition, some automation servers have an event mechanism ([Section 8.2, “OLE Events”](#)) that allows them to invoke methods in the OLE automation client. The `OLEObject` class also supports this mechanism.

Applications can provide OLE objects, and OLE objects that support automation can be used by a Rexx script to remotely control the object through the supplied methods. This lets you write a Rexx script that, for example, starts a Web browser, navigates to a certain page, and changes the display mode of the browser.

Every application that supports OLE places a unique identifier in the registry. This identifier is called the class ID (CLSID) of the OLE object. It consists of several hexadecimal numbers separated by the minus symbol.

Example: CLSID of Microsoft® Internet Explorer (Version 5.00.2014.0216):

```
"{0002DF01-0000-0000-C000-000000000046}"
```

The CLSID number can prove inconvenient when you want to create or access a certain object, so a corresponding easy-to-remember entry is provided in the registry, and this entry is mapped to the CLSID. This entry is called the ProgID (the program ID), and is a string containing words separated by periods.

Example: ProgID of Microsoft Internet Explorer: **"InternetExplorer.Application"**

To find the ProgID of an application, you can use the sample script **OLEINFO.REX** or the Microsoft OLEViewer, you can consult the documentation of the application, or you can search the registry manually.

Several sample programs are provided in the Open Object Rexx installation directory under **samples\ole**

- The apps directory contains examples of how to use Rexx to remote-control other applications.
- The oleinfo directory is a sample Rexx application that can be used to browse through the information an OLE object provides.
- In the adsi directory there are eight examples of how to use the Active Directory Services Interface with the Rexx OLE interface.

- The methinfo directory contains a very basic example of how to access the information an OLE object provides.
- Finally, the wmi directory contains five examples of how to work with the Windows Management Instrumentation.

8.2. OLE Events

Some, but not all, OLE automation objects support *events*. The most prevalent use of OLE is for the automation server (the OLE object) to implement methods that the automation client (the ooRexx OLEObject) invokes. However, it is also possible for the automation client (the ooRexx OLEObject) to implement methods that the automation server (the OLE object) invokes.

The methods that the automation client implements are called event methods and the automation server that supports event methods is called a *connectable* object. The connectable object defines the events it supports by defining the name of the method and its arguments, but does not implement the method. Rather the automation client implements the method. The client asks the automation server to make a *connection*. If the connection is established, then from that point on whenever one of the defined events occurs, the server invokes the event method on the connected client.

In effect, what is happening is that the automation server is *notifying* the automation client that some event has occurred and giving the client a chance to react to the event. Any number of clients can be connected to the same connectable object at the same time. Each client will receive a notification for any event they are interested in. There is no need for the client to receive notifications for every event. When the client is not interested in an event, the client simply does not implement a method for that event.

The original implementation of OLEObject allowed the Rexx programmer to use events in this way: The programmer defines and implements a subclass of the OLEObject. Within the subclass, the programmer defines and implements the event methods for which she wants to receive notifications. The programmer has the client make a connection to the automation server at the time the OLEObject object is instantiated ([Section 8.3.1, “new \(Class method\)”](#)) by using the **WITHEVENTS** keyword for the *events* argument. If the **WITHEVENTS** keyword is not used during instantiation, then no event connection can be made.

This is relatively easy to understand and a simple example should make this clear. In the following, rather than create a new OLEObject, the programmer defines a subclass of the OLEObject, a WatchedIE class. The WatchedIE object is instantiated with events. This tells the OLEObject to make an event connection, if possible. In the subclass, the programmer implements the events he is interested in receiving notifications for.

Example 8.1. OLEObject - WatchedIE

```
-- Instantiate an instance of the subclassed OLEObject
myIE = .WatchedIE~new("InternetExplorer.Application", "WITHEVENTS")
...

-- This class is derived from OLEObject and contains several methods
-- that will be called when certain events take place.
::class 'WatchedIE' subclass OLEObject

-- This is an event of the Internet Explorer */
::method titleChange
    use arg Text
    say "The title has changed to:" text

-- This is an event of the Internet Explorer
::method beforeNavigate2
```

```

use arg pDisp, URL, Flags, TargetFrameName, PostData, Headers, Cancel
...

-- This is an event of the Internet Explorer */
::method onQuit
...

```

However, the process described above only allows using events with OLEObject objects that are directly instantiated by the programmer. There are a number of OLE objects that support events, where the OLEObject object is not instantiated by the programmer, but rather is returned from a method invocation. Prior to ooRexx 4.0.0, events could not be used with these objects. In 4.0.0, methods were added to the OLEObject class that allow using events with any OLE object that supports events.

This second process works this way: With an already instantiated object, the programmer can create method objects for any events of interest and use the `addEventMethod()` ([Section 8.3.3, “addEventMethod”](#)) method to add the method to the instantiated object. Then the `connectEvents()` ([Section 8.3.7, “connectEvents”](#)) method is used to connect the automation client (the instantiated object in this case) to the connectable OLE automation server.

The following example demonstrates this second process that is available in ooRexx 4.0.0 and onwards.

Example 8.2. OLEObject - Watch Word

```

wordApp = .OLEObject~new("Word.Application")
wordApp~visible = .true
document = wordApp~documents~Add

-- Use the isConnectable method to ensure the object supports connections.
if document~isConnectable then do

    -- Create a method for the OLEEvent_Close event. From the Word documentation
    --and experimentation, it is known that this event has no arguments.
    mArray = .array~new
    mArray[1] = 'say "Received the OLEEvent_Close event."'
    mArray[2] = 'say "  Event has" arg() "parameters."'
    mArray[3] = 'say'

    mClose = .Method~new("OLEEvent_Close", mArray)

    -- Now add this method to the document object.
    document~addEventMethod("OLEEvent_Close", mClose)

    -- Tell the object to make an events connection.
    document~connectEvents
end

```

The preceding example brings up one last point that is important to note when defining event methods. It is possible for an event method to have the same name as a normal invocation method of the OLE object. This gives rise to this scenario:

The programmer adds an ooRexx event method to the OLEObject with that name. Then the programmer tries to invoke the normal method. However, the invocation will no longer get forwarded to the `unknown()` ([Section 8.3.22, “unknown”](#)) method. Instead the event method by the same name is invoked. This is the case in the above example. The document object has a `close()` method that is used to close the document. The document also has the `close()` event method that is used to notify clients that the document is about to close.

To prevent this scenario, when an event method of an OLE object has the same name as a normal method name, the programmer must prepend **OLEEvent_** to the method name. The implementation of `OLEObject` assumes the programmer has done so. If the programmer does not name the event methods using this convention, the results are unpredictable.

Note that *only* the event method names that have matching normal event names can be prepended with the `OLEEvent_` prefix. Other event names must not have the prefix. One way to check for this is to use the `getKnownEvents()` ([Section 8.3.11, “getKnownEvents”](#)) method. This method will return the correct names for all events the OLE object supports.

Example:

This example is a complete working program. To run it, Microsoft Outlook must be installed. The program demonstrates some of the various methods of the `OLEObject` that deal with events. The interface to the program is simplistic, but workable.

Once the program starts, the user controls it by creating specific named files in working directory of the program. This could be done for example using `echo`:

```
echo " " > stop.monitor
```

The three specific file names are: **stop.monitor**, **pause.monitor**, and **restart.monitor**. The `stop` file ends the program. The `pause` file has the program stop monitoring for new mail, but keep running. The `restart` file has the program restart monitoring from the paused state.

Example 8.3. OLEObject - Monitor Outlook

```
/* Monitor Outlook for new mail */
say; say; say 'ooRexx Mail Monitor version 1.0.0'

outLook = .oleObject~new("Outlook.Application")

inboxID = outLook~getConstant(olFolderInBox)
inboxItems = outLook~getNamespace("MAPI")~getDefaultFolder(inboxID)~items

if \ inboxItems~isConnectable then do
  say 'Inbox items is NOT connectable, quitting'
  return 99
end

inboxItems~addEventMethod("ItemAdd", .methods~printNewMail)
inboxItems~connectEvents

if \ inboxItems~isConnected then do
  say 'Error connecting to inbox events, quitting'
  return 99
end

monitor = .Monitor~new
say 'ooRexx Mail Monitor - monitoring ...'
do while monitor~isActive
  j = SysSleep(1)
  status = monitor~getStatus

  select
    when status == 'disconnect' then do
      inboxItems~disconnectEvents
      say 'ooRexx Mail Monitor - paused ...'
    end
    when status == "reconnect" then do
      inboxItems~connectEvents
      say 'ooRexx Mail Monitor - monitoring ...'
```

```

        end
        otherwise do
            nop
        end
    end
    -- End select
end
say 'ooRexx Mail Monitor version 1.0.0 ended'

return 0

::method printNewMail unguarded
    use arg mailItem
    say 'You have mail'
    say 'Subject:' mailItem~subject

::class 'Monitor'
::method init
    expose state active

    state = 'continue'
    active = .true
    j = SysFileDelete('stop.monitor')
    j = SysFileDelete('pause.monitor')
    j = SysFileDelete('restart.monitor')

::method isActive
    expose active
    return active

::method getStatus
    expose state active

    if SysIsFile('stop.monitor') then do
        j = SysFileDelete('stop.monitor')
        active = .false
        state = 'quit'
        return state
    end

    if SysIsFile('pause.monitor') then do
        j = SysFileDelete('pause.monitor')
        if state == "paused" then return "continue"

        if state \== 'quit' then do
            state = "paused"
            return 'disconnect'
        end
    end

    if SysIsFile('restart.monitor') then do
        j = SysFileDelete('restart.monitor')
        if state == 'continue' then return state

        if state \== 'quit' then do
            state = 'continue'
            return 'reconnect'
        end
    end

    return 'continue'

```

8.3. The OLEObject Class

The OLEObject class is a built-in class. No **::requires** directive is needed to use the class.

Methods available to the OLEObject class:

new (Class method)
 getObject(Class method)
 addEventMethod
 class
 CLSID
 copy
 connectEvents
 disconnectEvents
 dispatch
 getConstant
 getKnownEvents
 getKnownMethods
 getOutParameters
 hasOleMethod
 isConnectable
 isConnected
 ProgID
 removeEventHandler
 removeEventMethod
 start
 startWith
 unknown

Note: It is somewhat useful to think of the Rexx OLEObject object as a proxy to the real OLE object. The real OLE object has its own methods. Which methods it has is dependent on its individual implementation. These methods are then accessed transparently through the unknown() ([Section 8.3.22, “unknown”](#)) method mechanism of the OLEObject by invoking a method of the same name on the OLEObject object.

8.3.1. new (Class method)

Instantiates a new OLEObject as a proxy for a COM / OLE object with the specified *classID* (the **ProgID** or **CLSID**). If the COM / OLE object can not be accessed or created, an error will be raised. See the list of OLE specific errors in the Open Object Rexx Reference document.

Arguments:

The arguments are:

classID

The **ProgID** or **CLSID** that identifies the COM / OLE object to proxy for.

events

Controls how the event methods of the COM / OLE object are handled:

If the argument is omitted completely, then no action concerning the event methods is taken.

If the argument is NOEVENTS then the COM / OLE object is queried to determine if it is a connectable object. If it is, an internal table is constructed listing all the event methods. But the object is not connected.

If the argument is `WITHEVENTS` then the COM / OLE object is queried to determine if it is a connectable object. If it is, an internal table is constructed listing all the event methods, and an event connection is established.

getObject

A flag asking to first try to get an already instantiated OLE object, rather than instantiate a new object. Some OLE automation servers register themselves with the operating system when an object is first created, but not all do. If this flag is true, then the `OLEObject` first tries to proxy for an already running OLE / COM object. If this fails, then a new OLE / COM object is instantiated.

If the flag is omitted, or `.false` then no attempt to look for an already running OLE / COM object is made.

Example:

```
myOLEObject = .OLEObject~new("InternetExplorer.Application")
```

8.3.2. getObject (Class method)

This is a class method that allows you to obtain an OLE object through the use of a moniker. A moniker is a string and is similar to a nickname. Monikers are used by OLE to connect to and activate OLE objects. OLE returns the object that the moniker identifies.

If the object is already running, OLE will find it in memory. If the object is stored passively on disk, OLE will locate a server for the object, run the server, and have the server bring the object into the running state. This makes monikers very easy for the automation client to use. OLE hides all the details from the client. However, since the `OLEObject` also hides all the details when a new OLE object is instantiated, for the Rexx programmer there is not much difference between using the **getObject** method and using the **new** method.

Note that file system names are monikers. Therefore, if a file is associated with an application that is an OLE automation server, a new OLE object can be instantiated by using the file name as the moniker. Obviously, this is not true of every file. It is true for files like `.xls` and `.doc` files, for example, because Word and Excel are OLE automation applications.

The optional `class` argument can be used to specify a subclass of `OLEObject`, and can be used to obtain an OLE object that supports events (the '**WITHEVENTS**' option will be used in this case). This method is similar to the **new** method where the programmer supplies a ProgID or CLSID. In this case the programmer supplies a moniker.

Example 8.4. OLEObject - getObjectMoniker method

```
/* create a Word.Document by opening a certain file */
myOLEObject = .OLEObject~GetObject("C:\DOCS\HELLOWORLD.DOC")
```

8.3.3. addEventMethod

addEventMethod adds a new method to this object's collection of methods. The `name` argument specifies the name of the new method and the `methodObject` argument defines the method. The acceptable values for `methodObject` are the same as those for the second argument to the

setMethod method of the **.Object** class. That is, it can be a method object, a string containing a method source line, or an array of strings containing individual method source lines.

The purpose of this method is to add an event method to a OLEObject after the object has been instantiated. See the OLE Events ([Section 8.2, “OLE Events”](#)) section for more details on events.

Example:

Note that in this example, the printNewMail method is defined as a floating method. See the documentation for the **.methods** directory in the Open Object Rexx Reference book for more details if needed.

Example 8.5. OLEObject - printNewMail method

```
inboxID = outlook~getConstant(olFolderInBox)
inboxItems = outlook~getNamespace("MAPI")~getDefaultFolder(inboxID)~items

inboxItems~addEventMethod("ItemAdd", .methods~printNewMail)

...

::method printNewMail unguarded
  use arg mailItem
  say 'You have mail'
  say 'Subject:' mailItem~subject
```

8.3.4. class

If *self~hasOleMethod('class')* returns **.true**, then forwards to Windows, otherwise to superclass (ooRexx root class Object).

Note: to force resolution to the ooRexx root class Object, use the scope override option.

Example 8.6. OLEObject - use scope override option to resolve to ooRexx root class Object

```
... cut ...

clz=oleObj~class:.object    -- use method 'class' in the ooRexx root class Object

.. cut ...
```

8.3.5. CLSID

Returns the string value of the CLSID attribute, **.nil** if no value is present.

8.3.6. copy

If *self~hasOleMethod('copy')* returns **.true**, then forwards to Windows, otherwise to superclass (ooRexx root class Object).

Note: to force resolution to the ooRexx root class Object, use the scope override option.

Example 8.7. OLEObject - use scope override option to resolve to ooRexx root class Object

```
... cut ...

o=oleObj~copy::object    -- use method 'copy' in the ooRexx root class Object

.. cut ...
```

8.3.7. connectEvents

The connectEvents() method is used to connect the instantiated automation client (the OLEObject subclass object) to the automation server (the OLE object) at any time. The method returns **.true** if the connection was made, otherwise **.false**. Remember, not all OLE objects support events. The programmer can determine if the OLE object supports events by using the isConnectable() ([Section 8.3.15, "isConnectable"](#)) method.

Example 8.8. OLEObject - connectEvents method

```
wordApp = .OLEObject~new("Word.Application")
wordApp~visible = .true
document = wordApp~documents~Add

wordApp~connectEvents
```

8.3.8. disconnectEvents

This method disconnects from the connectable OLE object. The method returns **.false** if there is not a current connection, otherwise **.true**. After this method is called, the OLE object will no longer invoke the event methods, in effect stopping event notifications.

The internal data structures used to manage events remain intact. The programmer can use the connectEvents() ([Section 8.3.7, "connectEvents"](#)) method to reconnect at any time. Since the internal data structures do not need to be rebuilt, this will save some small amount of processor time. To completely remove the internal data structures use the removeEventHandler() ([Section 8.3.18, "removeEventHandler"](#)) method.

Example:

This example shows some code snippets from a program that monitors the user's inbox in Outlook. When a new mail item arrives, the user is notified. The interface for the program allows the user to turn off the notifications when she wants, then turn them back on later. When the interface signals the program to stop the notifications, the program simply disconnects the events from the Outlook object. When the user wants to resume notifications, the program reconnects the events.

Example 8.9. OLEObject - disconnectEvents method

```
outLook = .oleObject~new("Outlook.Application")
inboxID = outLook~getConstant(olFolderInBox)
inboxItems = outLook~getNamespace("MAPI")~getDefaultFolder(inboxID)~items

...
```

```

inboxItems~addEventMethod("ItemAdd", .methods~printNewMail)
inboxItems~connectEvents

...

select
  when status == 'disconnect' then do
    inboxItems~disconnectEvents
    say 'ooRexx Mail Monitor - paused ...'
  end
  when status == "reconnect" then do
    inboxItems~connectEvents
    say 'ooRexx Mail Monitor - monitoring ...'
  end
  otherwise do
    nop
  end
end
end
-- End select

```

8.3.9. dispatch

Dispatches a method with the optionally supplied arguments.

8.3.10. getConstant

Retrieves the value of a constant that is associated with this OLE object. If no constant of that name exists, the .Nil object will be returned. You can also omit the name of the constant; this returns a stem with all known constants and their values. In this case the constant names will be prefixed with a "!" symbol.

Example 1:

```

myExcel = .OLEObject~new("Excel.Application")
say "xlCenter has the value" myExcel~getConstant("xlCenter")
myExcel~quit
exit

```

Possible output:

```
xlCenter has the value -4108
```

Example 2:

```

myExcel = .OLEObject~new("Excel.Application")
constants. = myExcel~getConstant
myExcel~quit

do i over constants.
  say i="constants.i
end

```

Possible output:

```
!XLFORMULA=5
!XLMOVE=2
!XLTEXTMAC=19
...
```

8.3.11. getKnownEvents

Returns a stem with information on the events ([Section 8.2, “OLE Events”](#)) that the connectable OLE object supports. It collects this information from the type library of the OLE object. A type library provides the names, types, and arguments of the provided methods. The OLEObject object does not need to be currently connected to connectable OLE object.

This method will return the event methods for any connectable object. Prior to ooRexx 4.0.0, only OLEObjects created directly, and created with the 'event' flag (WITHEVENTS or NOEVENTS) would return any known events. This fact had not been fully documented. Therefore, if the user did not create the OLEObject correctly, .nil would be returned for objects that did support event connections.

In 4.0.0, the behavior is fixed (or enhanced depending on the point of view) so that the known events are returned for all connectable objects under all circumstances.

The stem provides the following information:

Table 8.1. Stem Information

stem.0	The number of events.
stem.n.!NAME	Name of n-th event.
stem.n.!DOC	Description of n-th event (if available).
stem.n.!PARAMS.0	Number of parameters for n-th event.
stem.n.!PARAMS.i.!NAME	Name of i-th parameter of n-th event.
stem.n.!PARAMS.i.!TYPE	Type of i-th parameter of n-th event.
stem.n.!PARAMS.i.!FLAGS	Flags of i-th parameter of n-th event; can be "in", "out", "opt", or any combination of these.

If no information is available, the .NIL object is returned. This indicates that the OLE object does support events.

Example script:

```
myIE = .OLEObject~new("InternetExplorer.Application","NOEVENTS")
events. = myIE~getKnownEvents

if events. == .nil then
  say "Sorry, this object does not have any events."
else do
  say "The following events may occur:"
  do i = 1 to events.0
    say events.i.!NAME
  end
end

exit
```

Sample output:

```

The following events may occur:
ONTEATERMODE
ONFULLSCREEN
ONSTATUSBAR
...

```

For an example of how to use events, see examples `samples\ole\apps\samp12.rex` and `samples\ole\apps\samp13.rex`. The samples directory is installed as part of the normal Windows installation.

8.3.12. getKnownMethods

Returns a stem with information on the methods that the OLE object supplies. It collects this information from the type library of the object. A type library provides the names, types, and arguments of the provided methods. Parts of the supplied information have only informational character as you cannot use them directly.

The stem provides the following information:

Table 8.2. Stem Information

stem.0	The number of methods.
stem.!LIBNAME	Name of the type library that describes this object.
stem.!LIBDOC	A help string describing the type library. Only set when the string is available.
stem.!COCLASSNAME	COM class name of this object.
stem.!COCLASSDOC	A string describing the COM class. Only set when the string is supplied by the type library.
stem.n.!NAME	The name of the n-th method.
stem.n.!DOC	A help string for the n-th method. If this information is not supplied in the type library this value will not be set.
stem.n.!INVKIND	A number that represents the invocation kind of the method: 1 = normal method call, 2 = property get , 4 = property put . A normal method call is used with brackets; for a property get only the name is to be specified; and a property set uses the "=" symbol, as in these examples: <code>object~methodCall(a, b, c)</code> <code>object~propertyPut="Hello"</code> say <code>object~propertyGet</code>
stem.n.!RETTYPE	The return type of the n-th method. The return type will be automatically converted to a Rexx object (see Type Conversion (Section 8.3.23 , "Type Conversion" in the description of the UNKNOWN method of the OLEObject class).
stem.n.!MEMID	The MemberID of the n-th method. This is only used internally to call the method.

stem.n.!PARAMS.0	The number of parameters of the n-th method.
stem.n.!PARAMS.i.!NAME	The name of the i-th parameter of the n-th method.
stem.n.!PARAMS.i.!TYPE	The type of the i-th parameter of the n-th method.
stem.n.!PARAMS.i.!FLAGS	The flags of the i-th parameter of the n-th method; can be "in", "out", "opt", or any combination of these (for example: "[in, opt]").

If no information is available, the .NIL object is returned.

Note that it is not required that an OLE object supply a type library. The methods of OLE objects that do not supply a type library can still be invoked by name, but there is no way for **getKnownMethods** to look up the methods. To use these OLE objects the Rexx programmer would need to consult the documentation for the OLE object.

In addition all OLE objects have methods that can only be used internally. There are mechanisms to *hide* these methods from the user, because they can not be used by the automation client. It is possible that these are not hidden properly and will be listed when using **getKnownMethods**. The following methods can not be used by an instance of the OLEObject:

AddRef
 GetTypeInfoCount
 GetTypeInfo
 GetIDsOfNames
 QueryInterface
 Release

Example 8.10. OLEObject - getKnownMethods method

```
myOLEObject = .OLEObject~new("InternetExplorer.Application")
methods. = myOLEObject~getKnownMethods

if methods. == .nil then
  say "Sorry, no information on the methods available!"
else do
  say "The following methods are available to this OLE object:"
  do i = 1 to methods.0
    say methods.i.!NAME
  end
end

exit
```

Sample output:

```
The following methods are available to this OLE object:
GoBack
GoForward
GoHome
...
```

8.3.13. getOutParameters

Returns an array containing the results of the single **out** parameters of the OLE object, or the .NIL object if it does not have any. **Out** parameters are arguments to the OLE object that are filled in by the OLE object. As this is not possible in Rexx due to data encapsulation, the results are placed in the array mentioned above.

Example:

Consider an OLE object method with the following signature:

```
aMethod([in] A, [in] B, [out] sumAB)
```

The resulting **out** parameter of the method invocation will be placed in the **out** array at position one; the "normal" return value gets processed as usual. In this case the method will return the .NIL object:

Example 8.11. OLEObject - getOutParameters method

```
resultTest = myOLEObject~aMethod(1, 2, .NIL)
say "Invocation result :" resultTest
say "Result in out array:" myOLEObject~getOutParameters~at(1)
```

The output of this sample script will be:

```
The NIL object
3
```

Out parameters are placed in the **out** array in order from left to right. If the above OLE method looked like this:

```
aMethod([in] A, [in] B, [out] sumAB, [out] productAB),
```

then the **out** array would contain the sum of A and B at position one, and the product at position two.

8.3.14. hasOleMethod

Queries whether a method named methodName exists. Returns **.true** if methodName exists, **.false** else.

8.3.15. isConnectable

Determines if the OLE object is a connectable object. In other words, does the OLE object support event methods and will it accept connections at this time. Not all OLE objects support events, probably the majority do not support events. This method returns **.true** if the object is connectable, otherwise **.false**.

Example 8.12. OLEObject - isConnectable method

```
outLook = .oleObject~new("Outlook.Application")

-- This searches all folders for the 'Mailbox - .. ' folder. Which is
-- usually the default folder in a business installation of Outlook.
nameSpace = outLook~getNameSpace('MAPI')
```

```

folders = nameSpace~folders
do i = 1 to folders~count
  if folders~item(i)~name~caselessPos("Mailbox") <> 0 then do
    theMailBoxFolder = folders~item(i)
    leave
  end
end

-- Now that we have the Mailbox folder, get the collection of folders that
-- are contained in the Mailbox folder.
folders = theMailBoxFolder~folders

if folders~isConnectable then do
  -- Add event methods to the folders object.
  ...
end

```

8.3.16. isConnected

Determines if the OLEObject instance is currently connected to a connectable OLE automation server. Returns **.true** if the instance is connected and **.false** if not.

Example 8.13. OLEObject - isConnected method

```

wordObj = .oleObject~new("Word.Application", "WITHEVENTS")
if wordObj~isConnected then do
  ...
end
else do
  ...
end

```

8.3.17. ProgID

Returns the string value of the ProgID attribute, **.nil** if no value is present.

8.3.18. removeEventHandler

Removes the event handler and cleans up the internal data structures used to manage events. No event methods will be invoked after this method is called. See the disconnectEvents() ([Section 8.3.8, "disconnectEvents"](#)) method for a way to temporarily disconnect from event notifications.

Example 8.14. OLEObject - removeEventHandler method

```

inboxItems~removeEventHandler
inboxItems~removeEventMethod("ItemAdd")

```

8.3.19. removeEventMethod

Removes the event method with the specified *name* that has been previously added to this object by the `addEventMethod()` ([Section 8.3.3, “addEventMethod”](#)) method.

Example 8.15. OLEObject - removeEventMethod method

```
inboxID = outlook~getConstant(olFolderInBox)
inboxItems = outlook~getNamespace("MAPI")~getDefaultFolder(inboxID)~items

inboxItems~addEventMethod("ItemAdd", .methods~printNewMail)
inboxItems~connectEvents

...

::method doneWithItemEvents private
  expose inboxItems

  inboxItems~removeEventHandler
  inboxItems~removeEventMethod("ItemAdd")
```

8.3.20. start

If `self~hasOleMethod('start')` returns **.true**, then forwards to Windows, otherwise to superclass (ooRexx root class Object).

Note: to force resolution to the ooRexx root class Object, use the scope override option.

Example 8.16. OLEObject - use scope override option to resolve to ooRexx root class Object

```
... cut ...

m=oleObj~start:.object(...)  -- use method 'start' in the ooRexx root class Object

.. cut ...
```

8.3.21. startWith

If `self~hasOleMethod('startwith')` returns **.true**, then forwards to Windows, otherwise to superclass (ooRexx root class Object).

Note: to force resolution to the ooRexx root class Object, use the scope override option.

Example 8.17. OLEObject - use scope override option to resolve to ooRexx root class Object

```
... cut ...

m=oleObj~startWith:.object(...) -- use method 'startWith' in the ooRexx root class Object

.. cut ...
```

8.3.22. unknown

The **unknown** message is the central mechanism through which methods of the OLE object are called.

For further information on the details on how an **unknown** method works, see *Defining an unknown Method* in the Open Object Rexx Reference.

The programmer can invoke the methods of the real OLE object by simply invoking the methods on the the Rexx (proxy) OLEObject object like this:

```
myOLEObject~OLEMethodName
```

This calls the method "**OLEMethodName**" of the real OLE object for any message (method) *that does not exist* in the Rexx OLEObject object through the *unknown* method mechanism. The implementation for the **unknown()** method in the OLEObject class does this by dispatching the method call to the real OLE object.

This presents a problem when an OLE object has a method with a name that is identical to a method defined for the OLEObject object. When this situation happens, the programmer has two choices.

One choice is for the programmer to call the **unknown** method directly. E.g., take an OLE object that has the method **copy** used to copy something from a source to a destination. Since **copy** is a method of the **Object** class, the copy method of the OLE object is a method name already defined for the OLEObject. The programmer can invoke the **unknown** method directly, like this:

Example 8.18. OLEObject - unknown method

```
msgArgs = .array-of("C:\open\myFile.txt", "C:\processDir\")
val = myOLEObject~unknown("copy", msgArgs)
```

This causes the implementation of the **unknown()** method in the OLEObject object to invoke the **copy** method of the OLE object with the arguments of **C:\open\myFile.txt** and **C:\processDir**.

The other thing the Rexx programmer can do is use the **dispatch()** ([Section 8.3.9, "dispatch"](#)) method. Since, in OLE automation terms, the act of invoking a method on the OLE object is commonly referred to as *dispatching* a message to the OLE object, this may make the code a little easier to understand. In the above example the **dispatch** method would be used like this:

```
val = myOLEObject~dispatch("copy", "C:\open\myFile.txt", "C:\processDir\")
```

8.3.23. Type Conversion

Unlike Rexx, OLE uses strict typing of data. Conversion to and from these types is done automatically, if conversion is possible. OLE types are called variants, because they are stored in one structure that gets flagged with the type it represents. The following is a list of all variant types valid for use with OLE Automation and the Rexx objects that they are converted from or into.

Table 8.3. OLE/Rexx Types

VARIANT type	Rexx object
VT_EMPTY	.NIL

VARIANT type	Rexx object
VT_NULL	.NIL
VT_ERROR	.NIL
VT_I1	Rexx string (a whole number)
VT_I2	Rexx string (a whole number)
VT_I4	Rexx string (a whole number)
VT_I8	Rexx string (a whole number)
VT_UI1	Rexx string (a whole, positive number)
VT_UI2	Rexx string (a whole, positive number)
VT_UI4	Rexx string (a whole, positive number)
VT_UI8	Rexx string (a whole, positive number)
VT_INT	Rexx string (a whole number)
VT_UINT	Rexx string (a whole, positive number)
VT_DECIMAL	Rexx string (a decimal number)
VT_R4	Rexx string (a real number)
VT_R8	Rexx string (a real number)
VT_CY	Rexx string (currency, a fixed-point number with 15 digits to the left of the decimal point and 4 digits to the right)
VT_DATE	Rexx string (a date)
VT_BSTR	Rexx string
VT_DISPATCH Rexx	OLEObject
VT_BOOL	.TRUE or .FALSE
VT_VARIANT	Any Rexx object that can be represented as a VARIANT
VT_UNKNOWN	OLEObject
VT_ARRAY *	Rexx Array
VT_BYREF *	Any Rexx object

* VT_ARRAY and VT_BYREF are combined with any of the other variant types and never used alone. VT_ARRAY and another variant type are used for a SAFEARRAY datatype, an array of the other variant type. VT_BYREF and another variant type are used to pass the other variant type to or from an OLE object by reference. The programmer need not worry about this passing by reference, the OLE support handles this transparently.

8.4. The Windows OLEVariant Class

The OLEVariant class enhances the support for OLE Automation provided by the OLEObject class ([Section 8.3, “The OLEObject Class”](#)) and is used in conjunction with that class. An OLEVariant object is used as a parameter in a method call of an OLEObject object. In the OLEObject's role as a proxy for a OLE / COM object, the parameters in method calls are forwarded on to the actual OLE / COM object. (OLE / COM objects will be referred to simply as COM objects.)

There are two areas where the OLEVariant adds to the capabilities of OLEObject method calls.

- Parameters forwarded on to COM objects must be converted to and from the proper datatypes. This conversion is done automatically (see [Section 8.3.23, "Type Conversion"](#).) Occasionally this automatic conversion is incorrect. The OLEVariant allows the ooRexx programmer to override the automatic conversion by specifying how the conversion should be done.
- COM objects can return data to the caller in "out" parameters ([OUT] parameters.) The OLEVariant can be used to transport this returned data back to the calling ooRexx program.

In general, the automatic type conversion in the OLE support uses type libraries to determine how to format the parameters being sent to an OLE object in a method call. The information in a type library specifies the variant type an ooRexx object, used as a parameter, needs to be converted to. Type libraries also detail how a parameter is to be flagged when it is sent to the COM object.

However, COM objects are not required to supply type libraries. When there is no type library, ooRexx uses an educated guess to determine this information. On rare occasions this guess is wrong and the method call fails. In these cases, if the ooRexx programmer knows what the correct information is, the programmer can use an OLEVariant to specify this information. The programmer can supply either or both of these pieces of information by specifying the variant type for the converted ooRexx object and the parameter flags.

The following is a real world example where the automatic conversion in the OLE support does not work and shows how the OLEVariant is used to specify the correct conversion. The snippet comes from code to automate a CICS client. In this case the variant type that the ooRexx object needs to be converted to is specified. The parameter flags are omitted. The fourth parameter to the ~link method call is the parameter where the default conversion was failing.

Example 8.19. OLEObject - automatic conversions

```
connect = .OLEObject~new("Ccl.Connect")
flow    = .OLEObject~new("Ccl.Flow")
buffer  = .OLEObject~new("Ccl.Buffer")

uow     = .OLEVariant~New(.nil, VT_DISPATCH)
...
connect~link(flow, "F00", buffer, uow)
```

Note

It is extremely rare that the OLE support fails to do the right thing with its automatic conversion. 99.999% of the time the ooRexx programmer does not need to use an OLEVariant object to specify the type conversion. This use of the OLEVariant is provided for those few times when it is necessary to override the default conversion. Furthermore, if the ooRexx programmer does not know what variant type to specify, this usage will not be much help. Normally the ooRexx programmer would know what type to specify through the documentation for the COM class the programmer is using.

The next example shows how the OLEVariant can be used to transport the data returned in an "out" parameter back to the calling ooRexx program. This usage will be more common and does not require that the ooRexx have a lot of detailed knowledge of the COM object. Obviously, the programmer does need to know that the parameter is an out parameter. This example comes from updating a MS Access database where the number of records affected by the update is returned in an "out" parameter. Here the out parameter is the second parameter in the ~execute method call.

Example 8.20. OLEVariant - new

```
sql = "update myTable set id=id*3 where id > 7"
param = .OLEVariant~new(0)
conn~execute(sql, param)
count = param~!varValue_
say count "record(s) were affected."
```

Finally an example where the OLE support does not use the correct parameter flags for the method call. The Windows Management Instrumentation, Win32_Process COM class does not supply a type library. The fourth parameter in the ~create method call is an "out" parameter. That information is known by the ooRexx programmer through the documentation of the class. However, without a type library, ooRexx has no way to know that. Here the variant type specification is omitted (signaling ooRexx to go ahead and use its automatic conversion) and the parameter flags are specified. Since this an out parameter, the OLEVariant object is also used to transport the returned data back to the calling program.

Example 8.21. OLEObject - incorrect parameter flags

```
objProcess = .oleObject~getObject("WinMgmts:Win32_Process")

param = .OLEVariant~new( 0, , "IN,OUT" )
ret = objProcess~create('notepad.exe', .nil, .nil, param)
if ret == 0 then do
    pid = param~!varValue_
    say 'The notepad process was created and its PID is' pid
end
```

Methods available to the OLEVariant class

```
new
!varValue_
!varValue_=
!varType_
!varType_=
!paramFlags_
!paramFlags=
```

**Note**

A possible future enhancement of the OLEVariant class requires that its method names be unique, which is the reason for the method name style. In normal usage the ooRexx programmer would only be concerned with the new and the !varValue methods. Therefore the slightly unorthodox method names should not present a problem.

8.4.1. new Class method

Instantiates a new OLEVariant object to be used as a parameter in an OLEObject method call. The first argument is the ooRexx object to be converted to a variant type for the method call. It is the object to be used in the method call. This argument is required. The varType and paramFlags arguments are optional.

The varType argument is used to specify the type of the variant that the valueObject is to be converted to. If this argument is omitted or is .nil then ooRexx will use the default conversion for the valueObject. If it is not omitted it must be a valid OLE Automation variant type and ooRexx will attempt to convert the valueObject to this variant type.

The valid variant type symbols are listed in [Section 8.3.23, "Type Conversion"](#). In addition any of those symbols can be combined with the VT_BYREF or the VT_ARRAY symbol. When symbols are combined a comma is used to separate the two symbols. This of course necessitates that the argument be quoted. Case does not matter for this argument. For example vt_bool, VT_bool, or VT_BOOL are all treated the same.

The paramFlags argument is used to specify the flags for the parameter. The flags are separated by a comma. Although any combination of valid PARAMFLAGS as defined for OLE Automation will be accepted, in practice the ooRexx programmer will probably only need to use "IN,OUT" for this argument.

The PARAMFLAGS defined for OLE Automation:

```

PARAMFLAG_NONE
PARAMFLAG_FIN
PARAMFLAG_FOUT
PARAMFLAG_FLCID
PARAMFLAG_FRETVAL
PARAMFLAG_FOPT
PARAMFLAG_FHASDEFAULT
PARAMFLAG_FHASCUSTDATA
  
```

The ooRexx programmer should only use the last portion of the symbol. I.e., NONE, IN, OUT, LCID, RETVAL, OPT, HASDEFAULT, or HASCUSTOMDATA. Case also does not matter for this argument and "in,out" is equivalent to "IN,OUT"

If the paramFlags argument is omitted or .nil, (the normal case,) ooRexx will determine the flags for the parameter through its default mechanism. If the argument is not omitted, ooRexx will use the specified flags unconditionally.

Note

If either the varType or paramFlags arguments are used, and not the .nil object, they must be valid variant types or param flags for OLE Automation. If they are not valid, a syntax error will be raised.

Example 8.22. OLEObject - parameters

```
manager = .oleObject~new("com.sun.star.ServiceManager", "WITHEVENTS")
cf = manager~createInstance("com.sun.star.reflection.CoreReflection")
...
classSize = .cf~forName("com.sun.star.awt.Size")

param = .OLEVariant~new(.nil, "VT_DISPATCH,VT_BYREF", "IN,OUT")

retVal = classSize~createObject(param)
```

8.4.2. !VARVALUE_

Returns the value object set within an instance of an OLEVariant. If the parameter in a COM method call that the OLEVariant was used for is an "out" parameter, then the value object of the instance will be the data returned by the COM object. Otherwise, the value object is that set by the ooRexx programmer.

```
manager = .oleObject~new("com.sun.star.ServiceManager", "WITHEVENTS")
cf = manager~createInstance("com.sun.star.reflection.CoreReflection")
...
classSize = .cf~forName("com.sun.star.awt.Size")

param = .OLEVariant~new(.nil, "VT_DISPATCH,VT_BYREF", "IN,OUT")

retVal = classSize~createObject(param)
size = param~!varValue_
```

8.4.3. !VARVALUE_ =

Sets the value object an instance of an OLEVariant contains.

8.4.4. !VARTYPE_

Returns the variant type specification of the OLEVariant instance.

8.4.5. !VARTYPE_ =

Sets the variant type specification of an OLEVariant instance. This serves the same purpose as the second argument to the new method ([Section 8.4.1, "new Class method"](#)) and follows the same rules as specified in the documentation of the new method. I.e., the value must be a valid variant type used in OLE Automation, or .nil. If not a syntax error is raised.

8.4.6. !PARAMFLAGS_

Returns the parameter flags specification of the OLEVariant instance.

8.4.7. !PARAMFLAGS_ =

Sets the flags specification of an OLEVariant instance. This serves the same purpose as the third argument to the new method ([Section 8.4.1, “new Class method”](#)) and follows the same rules as specified in the documentation of the new method. I.e., the value must be a valid combination of PARAMFLAG types as documented for use in OLE Automation, or .nil. If not a syntax error is raised.

Appendix A. Notices

Any reference to a non-open source product, program, or service is not intended to state or imply that only non-open source product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any Rexx Language Association (RexxLA) intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-open source product, program, or service.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-open source products was obtained from the suppliers of those products, their published announcements or other publicly available sources. RexxLA has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-RexxLA packages. Questions on the capabilities of non-RexxLA packages should be addressed to the suppliers of those products.

All statements regarding RexxLA's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

A.2. Source Code For This Document

The source code for this document is available under the terms of the Common Public License v1.0 which accompanies this distribution and is available in the appendix [Appendix B, Common Public License Version 1.0](#). The source code is available at <https://sourceforge.net/p/oorexx/code-0/HEAD/tree/docs/>.

The source code for this document is maintained in DocBook SGML/XML format.

The railroad diagrams were generated with the help of "Railroad Diagram Generator" located at <https://github.com/GuntherRademacher/rr>. Special thanks to Gunther Rademacher for creating and maintaining this tool.

Appendix B. Common Public License

Version 1.0

THE ACCOMPANYING PROGRAM IS PROVIDED UNDER THE TERMS OF THIS COMMON PUBLIC LICENSE ("AGREEMENT"). ANY USE, REPRODUCTION OR DISTRIBUTION OF THE PROGRAM CONSTITUTES RECIPIENT'S ACCEPTANCE OF THIS AGREEMENT.

B.1. Definitions

"Contribution" means:

1. in the case of the initial Contributor, the initial code and documentation distributed under this Agreement, and
2. in the case of each subsequent Contributor:
 - a. changes to the Program, and
 - b. additions to the Program;

where such changes and/or additions to the Program originate from and are distributed by that particular Contributor. A Contribution 'originates' from a Contributor if it was added to the Program by such Contributor itself or anyone acting on such Contributor's behalf. Contributions do not include additions to the Program which: (i) are separate modules of software distributed in conjunction with the Program under their own license agreement, and (ii) are not derivative works of the Program.

"Contributor" means any person or entity that distributes the Program.

"Licensed Patents " mean patent claims licensable by a Contributor which are necessarily infringed by the use or sale of its Contribution alone or when combined with the Program.

"Program" means the Contributions distributed in accordance with this Agreement.

"Recipient" means anyone who receives the Program under this Agreement, including all Contributors.

B.2. Grant of Rights

1. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free copyright license to reproduce, prepare derivative works of, publicly display, publicly perform, distribute and sublicense the Contribution of such Contributor, if any, and such derivative works, in source code and object code form.
2. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free patent license under Licensed Patents to make, use, sell, offer to sell, import and otherwise transfer the Contribution of such Contributor, if any, in source code and object code form. This patent license shall apply to the combination of the Contribution and the Program if, at the time the Contribution is added by the Contributor, such addition of the Contribution causes such combination to be covered by the Licensed Patents. The patent license shall not apply to any other combinations which include the Contribution. No hardware per se is licensed hereunder.
3. Recipient understands that although each Contributor grants the licenses to its Contributions set forth herein, no assurances are provided by any Contributor that the Program does not infringe the patent or other intellectual property rights of any other entity. Each Contributor disclaims any liability to Recipient for claims brought by any other entity based on infringement

of intellectual property rights or otherwise. As a condition to exercising the rights and licenses granted hereunder, each Recipient hereby assumes sole responsibility to secure any other intellectual property rights needed, if any. For example, if a third party patent license is required to allow Recipient to distribute the Program, it is Recipient's responsibility to acquire that license before distributing the Program.

4. Each Contributor represents that to its knowledge it has sufficient copyright rights in its Contribution, if any, to grant the copyright license set forth in this Agreement.

B.3. Requirements

A Contributor may choose to distribute the Program in object code form under its own license agreement, provided that:

1. it complies with the terms and conditions of this Agreement; and
2. its license agreement:
 - a. effectively disclaims on behalf of all Contributors all warranties and conditions, express and implied, including warranties or conditions of title and non-infringement, and implied warranties or conditions of merchantability and fitness for a particular purpose;
 - b. effectively excludes on behalf of all Contributors all liability for damages, including direct, indirect, special, incidental and consequential damages, such as lost profits;
 - c. states that any provisions which differ from this Agreement are offered by that Contributor alone and not by any other party; and
 - d. states that source code for the Program is available from such Contributor, and informs licensees how to obtain it in a reasonable manner on or through a medium customarily used for software exchange.

When the Program is made available in source code form:

1. it must be made available under this Agreement; and
2. a copy of this Agreement must be included with each copy of the Program.

Contributors may not remove or alter any copyright notices contained within the Program.

Each Contributor must identify itself as the originator of its Contribution, if any, in a manner that reasonably allows subsequent Recipients to identify the originator of the Contribution.

B.4. Commercial Distribution

Commercial distributors of software may accept certain responsibilities with respect to end users, business partners and the like. While this license is intended to facilitate the commercial use of the Program, the Contributor who includes the Program in a commercial product offering should do so in a manner which does not create potential liability for other Contributors. Therefore, if a Contributor includes the Program in a commercial product offering, such Contributor ("Commercial Contributor") hereby agrees to defend and indemnify every other Contributor ("Indemnified Contributor") against any losses, damages and costs (collectively "Losses") arising from claims, lawsuits and other legal actions brought by a third party against the Indemnified Contributor to the extent caused by the acts or omissions of such Commercial Contributor in connection with its distribution of the Program in a commercial product offering. The obligations in this section do not apply to any claims or Losses relating to any actual or alleged intellectual property infringement. In order to qualify, an Indemnified

Contributor must: a) promptly notify the Commercial Contributor in writing of such claim, and b) allow the Commercial Contributor to control, and cooperate with the Commercial Contributor in, the defense and any related settlement negotiations. The Indemnified Contributor may participate in any such claim at its own expense.

For example, a Contributor might include the Program in a commercial product offering, Product X. That Contributor is then a Commercial Contributor. If that Commercial Contributor then makes performance claims, or offers warranties related to Product X, those performance claims and warranties are such Commercial Contributor's responsibility alone. Under this section, the Commercial Contributor would have to defend claims against the other Contributors related to those performance claims and warranties, and if a court requires any other Contributor to pay any damages as a result, the Commercial Contributor must pay those damages.

B.5. No Warranty

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, THE PROGRAM IS PROVIDED ON AN "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, EITHER EXPRESS OR IMPLIED INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR CONDITIONS OF TITLE, NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Each Recipient is solely responsible for determining the appropriateness of using and distributing the Program and assumes all risks associated with its exercise of rights under this Agreement, including but not limited to the risks and costs of program errors, compliance with applicable laws, damage to or loss of data, programs or equipment, and unavailability or interruption of operations.

B.6. Disclaimer of Liability

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, NEITHER RECIPIENT NOR ANY CONTRIBUTORS SHALL HAVE ANY LIABILITY FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING WITHOUT LIMITATION LOST PROFITS), HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OR DISTRIBUTION OF THE PROGRAM OR THE EXERCISE OF ANY RIGHTS GRANTED HEREUNDER, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

B.7. General

If any provision of this Agreement is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this Agreement, and without further action by the parties hereto, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.

If Recipient institutes patent litigation against a Contributor with respect to a patent applicable to software (including a cross-claim or counterclaim in a lawsuit), then any patent licenses granted by that Contributor to such Recipient under this Agreement shall terminate as of the date such litigation is filed. In addition, if Recipient institutes patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Program itself (excluding combinations of the Program with other software or hardware) infringes such Recipient's patent(s), then such Recipient's rights granted under Section 2(b) shall terminate as of the date such litigation is filed.

All Recipient's rights under this Agreement shall terminate if it fails to comply with any of the material terms or conditions of this Agreement and does not cure such failure in a reasonable period of time after becoming aware of such noncompliance. If all Recipient's rights under this Agreement terminate, Recipient agrees to cease use and distribution of the Program as soon as reasonably practicable.

However, Recipient's obligations under this Agreement and any licenses granted by Recipient relating to the Program shall continue and survive.

Everyone is permitted to copy and distribute copies of this Agreement, but in order to avoid inconsistency the Agreement is copyrighted and may only be modified in the following manner. The Agreement Steward reserves the right to publish new versions (including revisions) of this Agreement from time to time. No one other than the Agreement Steward has the right to modify this Agreement. IBM is the initial Agreement Steward. IBM may assign the responsibility to serve as the Agreement Steward to a suitable separate entity. Each new version of the Agreement will be given a distinguishing version number. The Program (including Contributions) may always be distributed subject to the version of the Agreement under which it was received. In addition, after a new version of the Agreement is published, Contributor may elect to distribute the Program (including its Contributions) under the new version. Except as expressly stated in Sections 2(a) and 2(b) above, Recipient receives no rights or licenses to the intellectual property of any Contributor under this Agreement, whether expressly, by implication, estoppel or otherwise. All rights in the Program not expressly granted under this Agreement are reserved.

This Agreement is governed by the laws of the State of New York and the intellectual property laws of the United States of America. No party to this Agreement will bring a legal action under this Agreement more than one year after the cause of action arose. Each party waives its rights to a jury trial in any resulting litigation.
